Professor Parker Syms (New York) said that he had in his earlier operations approached the prostate by the suprapubic route, but he had come to the conclusion from anatomical considerations that the prostate was rather a perineal organ than one connected with the urinary bladder and that the only proper route by which to reach it was through the perineum. This was the direct rational and anatomical course and left the bladder entirely uninjured. He was sure that the surgeon should be guided by clinical aspects rather than by mere rectal examination. Residual urine and cystitis were certain to place the patient in jeopardy Whatever might be the amount and form of the enlargement of the prostate, he believed that every enlarged prostate could be removed through the perineum He demonstrated a special instrument which he had devised to render easy traction upon the prostate during its removal It consisted of a rubber tube to the further end of which was attached a collapsible rubber bulb, rather of an umbrella shape The apparatus was introduced into the bladder through the urethra and the terminal bulb was then inflated, thus producing a soft but very efficient retractor It further tended to arrest hæmorrhage during the progress of the enucleation He had operated on 21 cases All the patients except one had cystitis previously to operation, two had calculi, and in one case there were 54 ounces of residual urine and the patient was delirious with a temperature of 104° F He had lost no patient and all were completely relieved with no permanent incontinence of urine.

Mr **REGINALD HARRISON** (London) based his remarks on seven specimens of enlarged prostate which had been removed by the suprapubic route In five the results were entirely satisfactory, the patients recovering voluntary power over micturition. In the other two instances the results were not so good In one a cicatricial contraction occurred in the neighbourhood of the deep urethra and in the other carcinoma of the prostate supervened He had been much struck years ago by the amount of relief that many persons who were cut for stone obtained by the so-called accidental removal of portions of an enlarged prostate.

Sir **WILLIAM MACEWEN** (Glasgow) stated that after he had seen the large portions of the prostate which had been removed and exhibited by McGill of Leeds he had practised the suprapubic method, but in one instance because he had made a perineal incision for drainage, and had also noticed the benefit of the partial removal of the prostate in lithotomy, he began to make use of the perineal route. He not infrequently first performed perineal section, draining the bladder, and subsequently shelled out the lateral lobes by the same route, these not uncommonly shrinking after the section and before the enucleation

Mr **JORDAN LLOYD** (Birmingham) thought that the discussion had cleared up several doubtful points Prostates could be removed and the series of specimens shown by Mr Freyer demonstrated this absolutely The aim of the surgeon should be to arrive at an operation with the lowest mortality, shortest convalescence, and best after results.

Dr W E **HADDEN** (Portadown) and Dr G B **FERGUSON** (Cheltenham) having made a few remarks, Mr **FREYER** replied, congratulating the section on the eminently practical tone of the discussion and particularly on the excellent discourses of Professor Alexander and Professor Symes He would like again to emphasise his belief in the existence of two separate capsules to the prostate, so graphically described by Sir Henry Thompson many years ago as the result of 70 dissections He had no monopoly in prostatectomy, but he considered that partial removal had had its day and that his method was the best of the complete operation, as evidenced by what was removed and the entirely satisfactory after results

Mr T K **DALZIEL** (Glasgow) read a paper on

Gastro enterostomy for Simple Pyloric Obstruction.

He based his paper upon a series of 30 operations of gastro-enterostomy performed for simple pyloric obstruction causing incurable dyspepsia In 18 cases there was well marked inherent obstruction, while in eight others the stenosis was caused by external adhesions He considered it more satisfactory to resort to gastro enterostomy rather than to dilate or to divide the pylorus He gave details of the method of operating which he pursued

Dr G M **EDEBOHLS** (New York) read a paper on

Renal Decapsulation versus Nephrotomy

He advocated renal decapsulation, without incision into the renal substance, as a surgical method for the treatment of chronic Bright's disease The kidney having been exposed its capsule was to be incised on a grooved director, and the edges of the incision being caught up by forceps the capsule was to be widely stripped from the kidney surface by a rubber covered finger

Professor **CURATULO** (Rome) read a paper on

Photo therapeutics as a New Therapeutical Agent in Obstetrics and Diseases of Women

Being led by the good results obtained in general medicine with the use of photo-therapeutics Professor Curatulo had invented a speculum to facilitate their application to the uterus and vagina Incandescent light was composed of three different kinds of rays—viz, calorific, light, and chemical or actinic rays, and each kind had its own special physiological action. The chemical rays had been proved to be very beneficial in the treatment of lupus, anæmia, and chlorosis The speculum invented by Professor Curatulo enabled the three rays to be isolated and applied separately or all together The speculum was of the same shape as Ferguson's and was composed of a double tube of isometrope glass Two tubes communicated with the space left between the two walls constituting the speculum The vulvar extremity of the speculum was closed by an indiarubber cork, pierced to allow the passage of the wires to supply the electric incandescent lamp inside the speculum. The cork was also pierced by a thermometer so that the temperature of the interior of the speculum might be easily read. As blood prevented the passage of actinic rays the cervix was made anæmic by pressing the uterine extremity of the instrument against the cervix. If it was desired to apply all three kinds of rays simultaneously water was kept running between the two tubes of the speculum by means of a douche and an electric lamp of great intensity could then be used If the space was filled with ammonio-cupric solution the actinic rays alone would pass If it was filled with a red solution, such as cochineal, the actinic rays were absorbed and the luminous and calorific rays acted. The speculum could be used as a hot-air douche By moderate application of actinic rays important modifications of nutrition in cases of metritis and hypertrophy of the cervix might be obtained and they might be useful in cases of sterility due to ill development of the uterus and cervix. It also tended to facilitate absorption in parametritis and perimetritis The germicidal action might be of value in specific ulceration of the cervix and cancer

Dr G T **HARRISON** (New York) read a paper on

The Etiology, Diagnosis, and Treatment of Ectopic Gestation.

His remarks were mainly restricted to the diagnosis and treatment in the earlier months of pregnancy Treatment was guided by the following principles When the diagnosis was made before the death of the fœtus he advised removal of the genital sac by laparotomy as early as possible If rupture occurred operative interference or expectant treatment would depend on the character of the phenomena. In hæmatocele the medical man should await complications In total abortion with or without hæmatocele and retention of the dead ovum or tube treatment depended on the symptoms. If the tumour became hard and smaller per vaginam no surgical interference was indicated If the tumour grew larger and the patient became worse an operation was indicated Fever and suppuration demanded posterior colpotomy As regarded diagnosis, before death of the embryo he had noticed a peculiar soft elastic feel of the embryo If the fœtus was dead the tumour would be found to be hard and there would be discharge of dark blood per vaginam The commonest termination of tubal pregnancy was tubal abortion—complete or incomplete—rupture being a comparatively rare event

Professor **MURDOCH CAMERON** (Glasgow) thought that directly tubal gestation was diagnosed it should be operated on. He would not wait for complications In his experience the uterine membrane was more often expelled after the operation than before The text-book descriptions of tubal affections as being sausage shaped were all wrong In the large majority of hæmatoceles the embryo was dead. If it was alive the patient was very likely to die from hæmorrhage

Dr H. R **SPENCER** (London) thought that it was very important to point out what most gynæcologists knew, but many men in general practice did not, that the majority of tubal pregnancies were unruptured When they did rupture an immediate operation was required, when they did not no operation, as a rule, was necessary, although perhaps one might be better and convalescence more rapid Diagnosis was often most difficult He had lately had a case of tubal rupture seven days after the patient became pregnant. The cavity was not larger than a pea and the patient nearly bled to death He considered that tubal colic was a very important sign As regarded operation in the later months of pregnancy with living children, if all results were collected they would be found to be very bad One should never wait in hopes of getting a viable child. The only case in which he did this—the child being a little over six months—secondary rupture of the sac took place and the patient bled to death.

Professor J W BYERS (Belfast) thought with regard to the causation of this condition the attitude must be one of scientific scepticism In most cases there was no previous history of tubal disease. Ovarian pregnancy was fully established, perhaps some of those cases of missed periods with a very little collapse of which he had seen a good many belonged to this condition He favoured large injections of strychnine and saline solution together with local anæsthesia for the operation where there was much collapse

Dr A. DONALD (Manchester) said that it was very important not to expect a clear history of a missed period. If a pregnant tube was diagnosed operation was imperative. In hæmatoceles before operating it was advisable to wait for three weeks, as at the end of this time absorption often proceeded very rapidly In hæmatocele he would operate from the vagina and in all other cases by the abdominal route In one case he used both routes having cut down into a placenta from the abdomen he thought it better to leave it *in situ* and then by a vaginal operation to empty the sac and to pack it. From the abdomen he saw the sac contract down on his packing and the woman made an uninterrupted recovery

Dr W WALTER (Manchester) favoured the vaginal route for operation unless the patient was *in extremis*

Mr J H TARGETT (London) drew attention to the fact that in some cases there was antecedent disease of the tubes. One case he remembered in particular where the patient had had acute tuberculous peritonitis and this, together with the ascites made the diagnosis of tubal gestation very difficult. He had also noted cases where tubal swelling was quite anterior to the uterus and consequently the diagnosis was very difficult.

Dr C E PURSLOW (Birmingham) was of opinion that in diagnosis the most frequent error was to confound ordinary abortion with tubal gestation. He did not place much reliance on the discharge having seen numbers of cases where there had been amenorrhœa for three months

Dr J B HELLIER (Leeds) gave large doses of strychnine (35 minims) in collapse and intravenous injections of saline solution which, he thought, was a better method than the subcutaneous one. It would seem from Dr Harrison s paper that diagnosis of tubal gestation before rupture was much more exact in America than over here, as in his experience most cases of tubal pregnancy were not diagnosed before rupture or abortion.

Dr HARRISON replied

Dr R. JARDINE (Glasgow) read a paper on

The Use of Potassium Chlorate in Habitual Death of the Fœtus in the Later Months of Pregnancy

He considered that potassium chlorate had a beneficial action on the endometrium In these cases the placenta was always degenerated. Sir James Simpson was the first to point out the good results to be obtained from administering this drug in these cases and Dr Jardine having had a large experience fully agreed with him. It had been said that potassium chlorate would have an injurious effect on the blood but he had found no such drawback in these cases and he was in the habit of giving 10 grains three times daily after meals for six months with no ill-effects. He gave details of three cases. In one case that of a multipara with two former miscarriages at the fifth month and with no signs of syphilis, the patient came under his notice at the fifth month. He could hear the fœtal heart but noticed a large amount of liquor amnii. Potassium chlorate was given and a healthy child was born at full term with a macerated fœtus about five months old. In this case one fœtus having died he was just in time to stop the death of the other by administering potassium chlorate. In another case a multipara who had had several miscarriages came under his care and afterwards as long as she took potassium chlorate the children were born at full term if she neglected to do this then a miscarriage took place. At one of her labours the breathing after delivery with forceps and flooding became very bad and she appeared to be dying The pain in the left side was so bad that she asked to be turned on to her right. When he did this she at once recovered and he had no doubt that in moving her he had dislodged an air embolism. Lately she had refused to the take the drug because having had such bad times with full term children, she preferred miscarriages

The PRESIDENT (Dr D L ROBERTS) said that on Sir James Simpson s recommendation—he was always such a trustworthy observer—large numbers of practitioners had tried this treatment. Personally his results had always been unfortunate.

Mr J STUART NAIRNE (Glasgow) had had a large experience of this treatment and was sure that it was sound

Dr T A. HELME (Manchester) had been most disappointed with his results.

Dr SPENCER thought that in the first case mentioned the fact that one fœtus was dead was a proof that potassium chlorate in these cases was useless.

Dr. JARDINE replied.

Dr H. O NICHOLSON (Edinburgh) read a paper on

Puerperal Eclampsia in the Light of Thyroid Inadequacy and its Treatment by Thyroid Extract

After referring to the function of the active thyroid in supplying a secretion which was essential to the maintenance of the metabolic cycle, the constant enlargement of this gland to meet the needs of the increased metabolism incident to pregnancy was noted In some pregnant women the supply of iodothyrin in the tissues became gradually or suddenly insufficient for the purposes of metabolism. Then certain toxic substances entered the blood The toxic substances produced contraction of the blood vessels especially of the kidney and ultimately the flow of blood through the kidney being prevented suppression of urine and convulsions occurred. The toxins of eclampsia thus acted like toxic doses of digitalis and stopped their over excretion by producing intense contraction of the renal vessels Two main principles of treatment were clearly indicated (1) re adjustment of the process of metabolism to favour the complete metabolism of the nitrogenous substances and (2) re-establishment of the secretion of urine Thyroid extract by its well known influence on proteid metabolism fulfilled the first indication admirably The second indication was also best fulfilled by this remedy because in order to make the kidney secrete again it was necessary to relax the spasm of the renal arteries. Thyroid extract had been shown to possess a specific action in enlarging the calibre of the arteries and Dr Nicholson had shown that when this drug was given to eclamptic patients in sufficient doses to produce symptoms of thyroidism " the re-establishment of the secretion of urine was secured. Observations on the circulatory phenomena of normal and eclamptic pregnant women had shown that in the latter the radial arteries became contracted and the blood pressure was raised in the pre-eclamptic state The peripheral resistance increased steadily as convulsions became imminent. When the blood pressure was at its highest and the arteries were contracted the secretion of urine was at its lowest point. This among other things, supported the view that the toxins acted as powerful vaso-constrictors and more especially on the renal vessels

The PRESIDENT thanked Dr Nicholson for his valuable and interesting paper and he trusted that it would lead others to try the treatment recommended.

Mr R. H A. WHITELOCKE (Oxford) read a paper on

A Case of Intermenstrual Pain (Mittelschmerz) Cured by Two Successive Operations

The patient came under his observation after she had been treated a long while medicinally and also by dilating the cervix and curetting The pain was so bad that she was unable to do her work for 10 days before the period, the pain stopping 24 hours before the onset of the flow On examination Mr Whitelocke found an enlarged and cystic ovary and subsequently removed it. She got no better and coming under the care of Dr Spencer he detected a small fibroid in the fundus of the uterus which was not noticed at the first operation and an enlarged ovary This ovary Mr Whitelocke removed—it was cystic—and the patient made a perfect recovery

Professor BYERS thanked Mr Whitelocke for the able and scientific way in which he had discussed this subject.

Dr F McCANN (London) said that he was the practitioner mentioned in the paper He did not regard the case as one of mittelschmerz at all since the pain lasted up till the period, whereas in this disease there was a distinct interval. He regarded the patient as somewhat neurotic He had diagnosed fibroid and dysmenorrhœa and had dilated her If any radical operation was necessary he thought the uterus should have been removed and the ovaries left.

Dr SPENCER thought that the case was certainly one of mittelschmerz and that Mr Whitelocke had performed the best operation the second time, one ovary having already been removed and the other cystic.

Mr TARGETT thought that removal of the ovaries was quite the best treatment for these cases, especially when, too, the artificial menopause could be so well controlled by thyroid extract

Mr WHITELOCKE, in reply, stated that the pain did cease 24 hours before the period and therefore was a true case of mittelschmerz.

Mr NAIRNE read a paper on

So called Neurasthenia, Hysteria, and Abdominal Section,

and the meeting then adjourned to hear Professor W JAPP SINCLAIR'S Address in Obstetrics, which was published in THE LANCET of August 9th, p 341.

FRIDAY, AUGUST 1ST

Dr BERRY HART (Edinburgh) opened the discussion on

The Operative Treatment of Prolapsus Uteri

He first considered the anatomy of prolapsus, showing a sagittal mesial section of an advanced case. He contrasted this with the normal relations and then went on to show that prolapsus was really a hernia of a definite part of the pelvic floor—viz., that part in front of the anterior rectal wall where the posterior vaginal wall became separated from the anterior rectal wall—and that the peritoneum was driven in The side relations in an advanced case were not well known but there was no actual separation or tearing away from the fascia inside the obturator and levator muscles, but elongation of the broad ligaments, so that they lay almost vertically He pointed out that in the main one had to operate in the prolapsed position and had greater difficulty in doing anything to the supporting part He then described the operations necessary in a medium case—viz , amputation of part of the cervix, with anterior and posterior elytrorrhaphy Ventrofixations were also considered as well as Freund s vaginal implantation of the uterus and the radical operation of vaginal and uterine extirpation of Martin of Berlin and Martin of Birmingham. A number of casts of frozen sections and drawings were shown.

Dr G M EDEBOHLS (New York) noticed that all operators had now arrived at Dr Berry Hart's conclusions His own operation for prolapse of the second degree was curetting, amputation of the cervix, lateral colporrhaphies, and ventrofixation all at one sitting For complete procidentia he advocated total extirpation of the vagina and uterus, having now had considerable experience in the operation—eight cases all successful This operation was applicable to widows and to women past the menopause with the husbands' consent. It was an advantage to leave the tubes and ovaries if healthy as it left the peritoneum higher up By this operation a solid block of tissue five inches long was made between the bladder and the rectum He thought English operators let their patients lie a bed too long afterwards. He allowed his patients to get up at the end of a week and do what they pleased. He drew attention to the great advantages of lateral colporrhaphies over anterior and posterior

Dr MACNAUGHTON JONES (London) said that he did not like vaginal fixation. He showed two specimens of uteri from patients, aged 56 years and 74 years, upon whom he had performed hysterectomy for very severe procidentia, the last of 25 years' standing

Mr BOWREMAN JESSETT (London) advocated ventro fixation and repair of the pelvic floor both to be done at the same sitting, for cases of moderate prolapse In old women with prolapse he preferred hysterectomy

Dr W J SMYLY (Dublin) agreed with all that had been said but thought that more importance should be given to the difference between anteversion and retroversion. The latter was usually associated with prolapse and should be cured as soon as possible.

Dr McCANN recommended for cystocele extensive perineorrhaphy so as to extend the perineum forwards and this was best done by removing in addition to the mucous membrane the connective tissue as deep as possible

Dr J INGLIS PARSONS (London) advocated injection of the broad ligaments by quinine if repair of the pelvic floor failed He gave details of his operation and quoted the results of over 60 cases in many of which the patients had been operated on over two years, and some had since borne children. All the patients were cured, and most of them had been in a very bad state and had been operated on with no good result He found ventrofixation failed in old women with weak abdominal walls and interfered with pregnancy in young women, whereas his operation was free from both of these defects

Mr E S BISHOP (Manchester) pointed out that whereas the first step in prolapsus was always said to be retroversion it was really relaxation of the utero-sacral ligaments, and he described the operation which he was in the habit of doing to remedy this

Dr J TENNANT (Belfast) considered that a most important factor was the descent of the peritoneum forming the pouch of Douglas

Dr F EDGE (Wolverhampton) insisted on the importance of the fascia. This had not been sufficiently emphasised. Ventrofixation and Alexander's operation were quite sufficient in virgins and this showed what a little part the uterus took in prolapse. In primary uterine prolapse such as occurred in virgins the fascia was not involved After hysterectomy the proper method was to unite the various constituents of the pelvic floor in the same manner as hernia was treated He preferred Martin of Birmingham's operation to all others , it was much easier to remove the vaginal mucous membrane from above downwards

Dr COMYNS BERKELEY (London), being a colleague of Dr Inglis Parsons, had had an opportunity of seeing most of the cases mentioned in the latter's paper, both before the injection of quinine and a long while after, and he was able to state that the results of the operation had been all that Dr Parsons claimed for it

Dr A. L. GALABIN (London) advocated the use of the Hodge pessary for several years after most operations for prolapsus, since this condition occurred most frequently in the working classes and was due to their occupation, which they did not change after the operation, and he thought that this accounted for most of the bad results Where it could be obtained he thought enforced rest for many months after the operation would do instead of the Hodge pessary The operation which he had devised for this condition and with which he got the best results was to remove all the muscular wall of the vagina and central part of the levator ani and then to suture the lateral portions of the levator ani.

Dr BERRY HART replied.

Professor CAMERON read a paper on

The Treatment of Fibroids

He insisted on the importance of diagnosis and stated that only a third of his fibroid cases needed operative treatment In suitable cases he had never met with a bad result from double oöphorectomy and thought that it was an operation which was neglected and was sure it would again come into favour

Dr WALTER disagreed with oophorectomy for fibroids

Dr GALABIN favoured hysterectomy

Professor CAMERON replied

Professor CURÀTULO read a paper on

The General Therapeutic Indications of the Iodo-bromo saline Waters of Salsomaggiore (Italy)

He stated that the waters contained more iodine and bromine than any other water, five times more chloride of sodium than sea water, more lithium than the hot springs of Wheel Clifford in Cornwall, more strontium than the Dürkheim and Contrexéville springs, and what really gave the Salsomaggiore springs their supremacy over other similar waters was the large amount of bituminous substances they contained The treatment consists of baths of natural mineral water and acqua madre, local applications of mud, irrigations, and the vaginal steam spray Professor Porro was the first to point out the beneficial action of these waters in diseases of women and good results were generally obtained in pelvic inflammation, sub involution, endometritis, salpingitis, retroversion with adhesions, and fibroids, the hæmorrhage in the latter often being controlled Professor Curàtulo also described his new treatment of spraying the vagina and cervix for 20 minutes with the mineral waters by means of his steam spray apparatus and attributed his good results to the direct stimulation of the cells and the reflex excitement of the vaso-motor nerves caused by the mineral principles of the water, to the contraction of the blood-vessels and consequent relief of congestion, and to the absorption of iodine through the vaginal mucous membrane.

Dr McCANN read a paper on

Vaginal Fixation.

He fully described his method of operating and the cases suitable for it. He showed how it did not interfere with subsequent pregnancy and discussed its advantages. Illustrative cases were described. He had operated on 20 cases with complete success. In no case was any elevation of the temperature noted after the operation.

Professor C R. MARSHALL (Dundee) read a paper on the Abuse of Mercuric Chloride Solutions in Obstetric Practice.

STATE MEDICINE.

THURSDAY JULY 31ST

Tuberculosis and Notification

In opening the morning's session the PRESIDENT (Dr JAMES NIVEN Manchester) remarked that with the information concerning tuberculosis now in their possession he could confidently say that there was no infectious disease about which they knew so much for in no other infectious disease did they either know so exactly the mode of infection or the precise measures necessary for its prevention And this was fortunate, insomuch as the prevention of tuberculosis was infinitely more important than the prevention of any other of the infectious diseases the truth of this statement being obvious when he reminded the members of the section that something like one-seventh of the human race died as the result of tuberculous and therefore, preventable infection. Tuberculosis was in truth a preventable disease and the administrative measures required for its prevention although sufficiently simple in their general features were more complicated in detail than those employed in dealing with ordinary fevers the section therefore was fortunate in being able to listen first hand to the views of those two gentlemen who were the chief apostles of the movement for the prevention of the disease.

By what General Scheme of Action including Administrative Measures can the Prevention of Tuberculosis be most Efficiently Advanced?

Dr J ROBERTSON (Sheffield) before discussing the direct and indirect measures of administration which the question involved drew attention to the fact that no city in the empire had devoted so much attention to the subject of the prevention of the spread of tuberculosis as the city of Manchester, which city might also claim the honour of having been the first to take the field in the active campaign against this disease. Among the direct measures employed in the prevention of tuberculosis he drew attention to the necessity for the sanitary authority to know who were infectious and therefore likely to spread the disease. In Sheffield they had had voluntary notification since 1899 and in many other towns similar measures had been adopted. Personally he considered compulsory notification was both desirable and necessary not by including tuberculosis in the list of diseases which might be notified under the *Infectious Diseases Notification Act*, 1889 but by special clauses dealing with this disease alone for it would be a monstrous injustice if for example, a patient suffering from tuberculosis should be liable for a prosecution for exposing himself in a public place" as would a small pox patient in similar circumstances. In the course of his address Dr Robertson observed that if compulsory notification was wanted powers must at the same time be obtained authorising them to require that infectious matter from a consumptive person should be properly disinfected before being disposed of, in other words, the disinfection of sputum should be made obligatory on the person suffering or the person in attendance on the patient. He strongly urged that sanitary authorities should have power to establish places for the open air treatment of phthisis and other tuberculous diseases. As another administrative procedure he drew attention to the provision of isolation homes for cases that were a source of danger to their friends and to the general public, remarking that these homes would be useful in addition to the consumptive wards of workhouse infirmaries. With regard to indirect measures he put forward the better lighting and ventilation of houses factories, and workshops, better conditions as to air space and cleanliness round dwellings better food supplies and better conditions of labour

Dr ARTHUR NEWSHOLME (Brighton) continued the discussion and described in some detail the preventive measures which had been adopted at Brighton under the following headings Diagnosis Notification Disinfection Prevention of Infection Investigation of Sources of Infection, Removal of Insanitary Home or Work Conditions Removal of Patients to Sanatoriums &c. After treatment of Convalescents and Removal of Food Infection. He said that the health authorities examined suspected sputa gratuitously for the medical practitioners with the result that in 1901 125 such specimens were examined. With regard to notification, a fee of 2*s* 6*d* or 1*s* was paid for each case notified in private or public practice, the total number of cases notified in 1899 amounting to 113, whilst a fee of 6*d*. became due to the relieving officers for each intimation of the removal of a parochial phthisical patient to the workhouse infirmary Since 1893 it had been the routine practice in Brighton to disinfect the bedding and bedrooms of patients who had died from phthisis spitting was forbidden in or on the corporation tram cars cards, five inches by seven inches, containing a notice forbidding spitting except into proper receptacles, and stating that indoor expectoration on floors was the main source of spread of consumption were distributed to workshops, public-houses theatres, &c. to be affixed to the wall in some conspicuous position Enamelled metal plates with the same notice were now being prepared to replace these cards. Every notified patient received a card embodying simple precautions of a non-alarmist character the poorer patients were supplied with sputum bottles and Japanese handkerchiefs free of charge. In Brighton the local branch of the Charity Organisation Society now paid for two beds in an institution for the open air treatment of phthisis the town council of Brighton in addition paying for three patients. This Dr Newsholme considered would enable Brighton to keep 12 patients per annum at a cost of about £470 They had also commenced the treatment of patients in small isolation pavilions attached to the local fever hospital and he expressed it as his conviction that the treatment of such cases in fever hospitals during the inter epidemic periods would in the near future, form an important branch of public health work.

Dr JAMES BEATTY (Manchester) next described the measures that had been adopted in Manchester for the investigation and control of tuberculous cases. He explained the method of notification which was in vogue, emphasising the fact that although the notification of this disease was practically a voluntary one the health authorities of Manchester had been enabled during the past year to obtain information about a large number of cases. As soon as a case was notified it was visited by the assistant medical officers of health and every endeavour was made to obtain full data as to the causation and course of the disease especially with regard to the source of contagion and possible relationship to the conditions of work. Instructions were given to the patients as to the means to be adopted to render themselves less liable to serve as centres of infection and therefore a source of danger to their fellows In certain cases the patients were transferred to healthier surroundings than obtained in their own homes the otherwise empty small pox hospital had been utilised for the reception of some of these patients with excellent result in spite of its bad situation but the space at the disposal of the sanitary authorities of Manchester was quite inadequate to accommodate the entire number A thorough system of disinfection was also in vogue in some cases complete disinfection of the rooms occupied by tuberculous patients was carried out by the sanitary authorities whilst in suitable cases the tenants were encouraged to employ a modified disinfection which consisted of lime-washing the ceilings &c. cleaning the walls and scrubbing the floors with soap and water

Dr C R. DRYSDALE (London) inquired as to the number of deaths per annum in Manchester from phthisis.

In reply the PRESIDENT stated that about 1200 deaths from tuberculosis were returned for the past year but the death rate for tuberculosis had steadily diminished for the past 30 years. The diminution was perhaps not rapid, but at the same time the improvement in this respect was really greater then might at first be apparent a an entirely new generation was now being dealt with and the population itself might justly be regarded as offering greater facilities at the present time for the spread of tuberculosis than it did a generation ago.

Mr W HODGSON (Crewe) referred to the recent conference of the representatives of all the sanitary authorities for the county of Cheshire who were endeavouring to obtain the permission of the Local Government Board for the erection of large sanatorium in spite of the fact that tuberculosis with them was not a compulsorily notifiable disease He spoke of the difficulties which surrounded the attempts of those responsible for the public health to secure the sympathy and coöperation of public bodies in such measures

Dr RANSOME (Bournemouth) pointed out the fact, which he feared was too much overlooked, that tuberculous infection was much more largely conditional on individual resistance than the infection of many other diseases and it no doubt frequently happened that an individual might harbour virulent tubercle bacilli and yet, provided he himself was strong and healthy and lived in healthy surroundings, the chances were largely in favour of that individual not contracting the disease. In support of his contention that the tuberculous infection was conditional upon the receptivity of the body and to an almost equal extent on the environment of that body Dr Ransome mentioned some experiments in which a sample of tuberculous sputum exposed to sunshine and air in his own house had entirely lost its virulence in the course of a few days, whilst a similar sample of the same sputum exposed in the room of one of the lower class houses in Manchester contained living virulent bacilli at the end of three weeks He would like to urge upon the medical officers of health that their great duty with respect to the prevention of tuberculosis was to improve the conditions of life—and especially the conditions of the dwellings—of the poor This was the true English method of fighting the disease, in contra distinction to which notification, whether partially or absolutely compulsory, and hospital treatment, might be termed the continental method Whilst he looked for the best results from a happy combination of the two, he once more urged the extreme importance of the improvement of the home surroundings of the indigent tuberculous population.

Dr A. D WEBSTER (Edinburgh) expressed his opinion that they were going too far in attempting to place tuberculosis in the same category as scarlet fever and small pox, for that was undoubtedly the tendency of this plea for notification, and he thought that more good would be done by not attempting to make notification compulsory The numerous cases of local tuberculosis which came under the observation of the general practitioner and the good results which usually followed upon treatment, pointed to the curability of the disease, and he would urge the injustice done them by labeling such patients as contagious

Dr DRYSDALE feared that improvement would not follow any measures, such as notification or treatment in sanatoriums, until the condition of the people, and especially the poor people, was improved. Phthisis and poverty went hand in hand, and until overcrowding had become a thing of the past phthisis could never be banished At the same time he believed that if such measures as were in vogue in Manchester and Brighton were more generally adopted, the amount of consumption existent in England would be materially diminished

Mr J F HALL-EDWARDS (Birmingham) believed that the establishment of sanatoriums was the best means of stamping out phthisis, at present, however, they appeared to be fostering consumption as a hothouse plant rather than treating it as a scourge. He was strongly opposed to methods which entailed the treatment of tuberculous patients for a limited time in sanatoriums and which then simply returned them to that identical home environment which was in so large a measure responsible for the disease. From his knowledge and experience of South Africa he was convinced that there was the ideal place for the erection of sanatoriums, which should take the form of working colonies for consumptive people rather than sanatoriums such as they erected in England, there such patients might live practically entirely in the open air and at the same time contribute their quota to the resources of the colony He would further suggest that the Government might reasonably be requested to allow the use of some one or two transports for the purpose of conveying these patients to South Africa.

Dr J LLOYD ROBERTS (Colwyn Bay) considered that treatment in sanatoriums was the best way of dealing with the tuberculosis question, although he realised the force of Dr Ransome's arguments for general improvement of the home surroundings of the people. Consumption might truly be said to originate in the dwellings of the poor, and therefore the better housing of the working classes was a most important preventive measure.

Dr J M RHODES (Manchester) also remarked on the intimate connexion existing between the housing problem and the prevention of tuberculosis

Dr ROBERTSON then proposed the following motion —

> That this section of the British Medical Association considers that the time has now come for the Local Government Board to grant more extended powers for dealing with cases of tuberculosis to such local authorities as are able to show that they are in a position to undertake the necessary work

This motion was seconded by Dr NEWSHOLME and unanimously adopted

The Relation of Poverty to Disease

Mr Alderman M'DOUGALL, deputy chairman of the sanitary committee of the Manchester corporation and a member of the Manchester board of guardians, read a paper embodying the results of his observations on this subject, with especial reference to the township of Manchester For the purpose of comparison he divided Manchester into three districts—viz, Manchester township, North Manchester, and South Manchester The inter relationship of these three districts with respect to poverty had been arrived at by comparing the death rates of persons from each district as obtained from the workhouses and hospitals and other charitable institutions These figures showed that the township contained a much larger proportion of persons in conditions of poverty than either of the other two districts, whilst South Manchester had a much greater proportion than North Manchester By means of an excellent series of diagrams he showed that the higher death rate always present in the more impoverished districts indicated that poverty tended to the increase of disease, and accelerated death Other influences affected the death rate in each district, but when these were taken into account there remained a very large amount of injury to life that could only be the result of the active effects of poverty After an extended examination of the statistics, Mr M'Dougall said that it was much more easy to point out dangers and injuries to health than to suggest measures of protection and remedy, the causes of poverty were so various and much of the suffering and disablement came to many who were not themselves transgressors, and, further, such an examination as he had undertaken quite failed to distinguish between poverty due to inadequate means and poverty arising from wastefulness Intemperance, idleness, carelessness, and ignorance brought poverty and distress to children and dependents Accident and physical incapacity also impoverished some who otherwise would be self-supporting Changes in trade, national calamities, and unfavourable seasons removed opportunities of earning from willing workers The economic problems of wealth and poverty were always present Something, however, might be done in mitigation of the more visible effects of ill health. Young children formed the class of those who endured poverty whose condition was most susceptible of mitigation Improvement of condition would be certain to result to a large number of children if mothers became more capable of making the best of what food could be obtained He believed that it would be of immense service to public health if every girl attending elementary schools had as part of her education during the last year of her school life to learn practical lessons in cooking simple foods and the details of cleanly and economical use of the fireplace and household utensils. At the same time the methods of cleansing the house could easily be taught It would be a profitable expenditure of educational finance in State aided schools that food materials should be purchased of sufficient quantity to give one good meal in the day to the most needy of the scholars, this to be cooked by the elder girls under efficient supervision Such training of girls before leaving school would also have a good effect in their homes whilst they were still scholars The periodical taking of the weight and height of scholars would be useful as pointing out deficiency of food or of other necessaries To prevent much of the worst kind of poverty among men and women during working age, earnest efforts were required to prevent intemperance by the removal of temptations and inducements to drink, and also to foster a strong public opinion against gambling There should be appreciative support of the authorities in their attempt to improve the sanitary condition of dwelling-houses and to remove the causes of overcrowding, as from the figures which he had given and from statutory enactments it was clearly their duty to make special efforts in connexion with such conditions in the poorest parts of our large towns The encouragement of cheap transit to the suburbs and the provision of open spaces were in this connexion of much importance He believed the day would come when, in addition to savings banks they would have banks granting small loans to workers on a rate of interest not much beyond that payable on deposits, the loans to be granted on approved personal security of friends and repayable in weekly instalments, a system already in practice in Manchester and yielding most excellent results. For aged persons of 65 years and upwards in necessitous circumstances he was convinced that much could be done by existing boards of guardians undertaking to deal with applications for aid from persons who have attained 65 years of age, quite apart from the applications of persons under that age and he would recommend that boards of guardians should appoint special committees to consider all requests for aid from aged persons, such committee could discriminate and make grants suitable to the condition of the applicants. Some would be selected as fit for grants of weekly sums say of 5s in orders extending over six months and renewable if satisfactory, others not in a condition to expend money or to attend to their own personal needs might be selected for maintenance in homes apart from the workhouses others suffering from ailments needing hospital treatment could be received into the workhouse hospitals, and when able to be out of bed should have the use of special day rooms. The remainder should be dealt with as at present in the workhouses. The first three classes would undoubtedly involve a higher expenditure by the ratepayers than the present system for many persons who did not now apply to the guardians would most gladly accept aid in one of the three forms he had mentioned That being so he considered that it would be only right for the State to bear part of the cost The select committee of which Mr Chaplin, then President of the Local Government Board was chairman reported in 1899 in favour of contributions to Poor law unions which might appoint special committees empowered to make weekly grants to aged persons, such contributions not to exceed one-half of the cost of the grants. It was obvious that this recommendation for a modified form of provision for necessitous old age only applied directly to a limited number of persons, but he was of opinion that if it were adopted it would have a beneficial effect on poor persons at ages less advanced.

Mr B SEEBOHM ROWNTREE (York) followed Alderman M Dougall with a paper on the same subject, in which he detailed his investigations in the city of York which was taken as a fairly typical provincial town. The immediate purpose of this inquiry was to throw some light on the questions What proportion of our town populations are living in poverty? What are the chief immediate causes of that poverty? What are the effects of poverty on health? In order to obtain accurate information the investigation included a house-to-house visitation of every working-class house in York. By this means much detail was obtained in each case regarding the number and ages of the occupants the number and occupation of the wage-earners and the accommodation and rent of the house, together with certain data as to food &c. Furnished with this information and with knowledge obtained through other channels Mr Rowntree was able to make a fairly accurate estimate of the earnings of every working-class family in York. In the first place it was necessary to determine what constituted poverty and for the purposes of this investigation he had taken as his working basis the lack of essentials for merely physical efficiency that is such quantity of food as would be just sufficient to enable an adult to do moderate work, together with appropriate allowance for rent and clothing It would be noted that in this estimate he allowed for no beer no tobacco no relaxation, but had in fact, only taken into account just so much nourishment as was absolutely necessary to provide the requisite number of calories. In analysing the data he had obtained he came to the conclusion that a family of ordinary size consisting of wage-earner wife, and two or three children, necessitated the expenditure of at least 21s. per week to maintain simply and barely physical efficiency The results obtained were very analogous to those recorded by Mr Charles Booth who had stated that fully 30 per cent of the people in London were living in poverty and this figure might be accepted as an under-estimate rather than an over-estimate of the poverty in York. If it was recollected that at the last census 77 per cent. of the total population of England and Wales was returned as urban and only 23 per cent. as rural the seriousness of the fact that more than a quarter of the town population was living below the poverty line would be at once realised. The answer to the second question that he had set himself What are the chief immediate causes of poverty? might be briefly summarised by saying that no less than 51 96 per cent. of the cases of poverty were due to low wages a startling commentary on the prevalence of unskilled labour the next chief cause which was responsible for 22 16 per cent was excessive size of family The death of the chief wage earner was responsible for the poverty of 15 63 per cent. of the cases, in 5 11 per cent poverty was directly due to the illness or old age of the bread winner whilst in only 2 83 per cent was it due to irregularity of work and in 2·31 per cent. to total loss of work. Mr Rowntree developed the third part of his thesis concerning the effects of poverty on health by analysing the result of the physical examination of a large number of school children (nearly 2000) and by discussing the figures obtained from the local recruiting stations The children living in poverty showed a marked contrast to those placed in happier circumstances with regard to height and weight at the age of 14 years the boys showed a deficiency of some three inches as compared with the average normal standard and some nine or 10 pounds in weight results undoubtedly due to underfeeding

On the motion of the PRESIDENT a hearty vote of thanks was accorded to Mr Alderman M Dougall and Mr Rowntree for their papers.

In the discussion which followed Dr DRYSDALE argued that where there was a low birth rate there would be prosperity amongst the people, for he contended the birth rate regulated the death rate where there was a high birth rate there was always a high death rate and this could easily be proved on figures obtained from any town one liked to mention Dr Drysdale concluded from this that it was impossible to ameliorate the condition of the working classes so long as the birth rate was so high

Dr RHODES *controverted Dr Drysdale's argument, stating* that it was unsound or if true Ireland with its low death rate, ought to be an extremely prosperous country The connexion between pauperism and disease was extremely important, and he was glad to know that it was being made the subject of exact scientific inquiry that it was no longer considered sufficient to take these two conditions as the act of God but that workers were endeavouring to find the causes to know what they were and how they arose *As an American writer had said,* To cure was the voice of the past—to prevent, the Divine wisdom of to-day " Some did not realise the enormous part which hospitals played in the amelioration of poverty and disease. There were to-day in the London workhouse hospitals about as many deaths as in all the voluntary hospitals of England and Wales put together This showed the awful mass of misery and poverty in this country At the same time he did not agree that there was need to be despondent. There was an idea that our age had been productive of new evils he thought rather that what were really new were the intellect that discerned and the humanity that remedied the evils. With regard to the conditions of the people, he thought that overcrowding and bad atmosphere produced depression and this produced a craving for drink and thus they got disease. He believed that a vast amount of misery was due to the vagrant class They played a prominent part in spreading disease and he would like to see a Royal Commission appointed to inquire into this class of poverty He commended the suggestion of Mr Alderman M Dougall in regard to loans, which he thought a good one. He believed that underfeeding played an important part in the production of disease. Dr Rhodes also believed that ladies by buying goods produced by sweated labour helped to produce poverty Thousands and thousands of shirts were made to-day at 9d a dozen. He thought that they should have to go in for women's trade-unions *The number of unskilled labourers and workmen, he added* was enormous The unskilled man was continually put out of work by machinery he instanced the navvy and the road sweeper Dr Rhodes in concluding advocated more education and the teaching of sanitation producing more skilled workmen and hygienic condition. By this means he believed, they would see in a few years an enormous reduction in the amount of disease and lot poverty

PSYCHOLOGICAL MEDICINE.

WEDNESDAY JULY 31ST (*continued*)

Dr C HUBERT BOND (London County Asylum Bexley) read part of a paper dealing with the *Hospital Treatment of Patients at the Bexley Heath Asylum* including plans and descriptions of villas used fo convalescing and quiet chronic cases The system of nursing was like that in the medical wards of hospitals Plans of the villas for the housing of chronic quiet patients and of the gardens were shown as well as the charts used for the daily records of the condition of recently admitted patients while under observation in the special hospital wards of the asylum. In the discussion which followed,

Dr J **RUTHERFORD** (Dumfries) remarked that the villa system of housing convalescent and quiet chronic cases of insanity was good and that accidents were few

Dr **ROBERT JONES** (London County Asylum, Claybury) spoke of the usefulness of charts showing the nightly hours of sleep for each patient during six weeks after admission and stated that improvement often occurred as insomnia grew less

Mr G W **MOULD**, the President (Cheadle), said that the system of housing patients in detached blocks or villas had been employed by him at the Cheadle Royal Asylum during the previous 25 years and that nearly two thirds of all the patients were so housed with beneficial results

THURSDAY, AUGUST 1ST

Professor **CLIFFORD ALLBUTT** (Cambridge University) opened a discussion on the

Relation of Functional Neuroses (Hysteria, Neurasthenia, Hypochondriasis, &c) to Insanity

Diagrammatically they might conceive of the nervous system as a vertical pile of centres, the lowermost of which presided over the earliest of the functions, each higher centre in its turn being occupied with functions later and later in the order of development Not only so, but each later centre was not only attached directly to its predecessor but was coordinated also with all its predecessors so that the pile became a system of mutual interdependence. Thus every later centre modified, or in other words controlled or inhibited, not only the one immediately below it but also each and all the earlier centres, certain cardinal inhibitions being provided for by special short circuits Thus, for example, sphincters became inhibited by higher motor centres and these in their turn by centres of still higher levels But a nervous centre was not a mere change house, it was also an accumulator of energy, whereby it was prepared not only for mean demand but also for extremes of effort or rest It was not only a fly wheel, which did not enlarge as the output of its engine increased, but rather like a bank which, as the output of the body increased, became itself enriched for direct expenditure, mutual reinforcement, and inhibition. In capacity of enrichment by way of expenditure individuals differed widely, in some an excessive run might strain the central resources so far that even the needs of ordinary functions were met with difficulty In one man a certain measure of work not only achieved the immediate end but also enriched his reserve of energy, in another, if it achieved the immediate end, it fell short of addition to the reserve, in a third the end was achieved at the cost of depleting the reserve, in the fourth even the immediate end was not attained and the reserve was not only exhausted but its elasticity was so impaired that for some time to come it was unable to keep up with current work. The neurasthenic had never much reserve for time of stress, he needed inordinate time for repair and was apt to be exhausted beyond the possibility of full repair In this lowering of nervous potential not only did output soon run down but inhibition was slackened so that energy was prematurely set free in what they called "irritable weakness" All the functions seemed to be upon the hair trigger This, however, was insanity, it was not perversion but poverty In an insane person sleep restored the manifestations of a distorted mind, by sleep and food neurasthenia was remediable. Hysteria, on the other hand, [illegible] was not the snapping off of inhibition at half cock but the [illegible] interference of inhibition out of season. It consisted in [illegible] intrusive suggestion, the patient could not take the break [illegible] off, so it was often remediable by counteracting suggestion [illegible] of disciplinary exercises, neither of which were of [illegible] service in neurasthenia In hysteria, then, certain controls were [illegible] in relative excess—the patient was "possessed. The neurasthenic expended his talent, the hysteric wrapped it in a napkin Hypochondriasis was neither neurasthenia nor insanity, though in its fixed idea it was nearer to it than either In practice, however, the line was not crossed so often as the student might expect The neurasthenic sought each new physician with fresh prospects of relief, the hypochondriac sought him only to consume another man's time and sympathy upon the altar of himself The morbid states and processes, to which they gave names such as these, were of course somewhat arbitrary conceptions at best, no disease was separated by a definite line from another In neurotic persons and families the distinctions between the disorders they had mentioned and insanity melted at their edges, or, again, any two or all three of them might conceivably occupy the same individual system, and a thread of insanity might also be woven into the same fabric, a discriminating diagnosis of so complicated a condition might be difficult or impossible More frequently, however, the difficulty was rather one of a more intimate diagnosis, confusion generally depended not upon identity but upon a similarity between two or more of these maladies in certain phases of their periods For instance, the obsessions of neurasthenia, though usually different from those of insanity, might at times be hard to distinguish and diagnosis could only be made by analysis of all the features past and present. An insanity, again, might be regarded as the issue of a previous neurasthenia, whereas the disorder had been an insanity from the beginning Occasionally the discrimination of neurasthenia from certain stages of melancholia, of delusional insanity, of general paralysis, of the malaise of some visceral disease, or from the sequel of some infection might be difficult to establish. Confusion was often made worse by the habit of taking names in their mere etymological sense, forgetting that as their clinical conceptions became more definite these names acquired more complex derivative meanings So they were apt to apply the name "neurasthenia" to any sort of weakness in which nerves were concerned, and in what weakness were the nerves not concerned? For instance, the so-called neurasthenia of high arterial pressure was not neurasthenia at all, it might be melancholia or some intoxication, nor was the state of listlessness and misery which followed influenza neurasthenia—it was influenza still, the dizziness and fretfulness of atonic dyspepsia were attended with nervous debility, but they did not make neurasthenia The initial stages of delusional insanity in a person of a certain temperament might be very difficult to distinguish from neurasthenia, but a temporary similarity was not identity In a particular case, again, the speaker found himself unable for a couple of years to form a decided opinion between general paralysis and neurasthenia, the former diagnosis proving to be the true one. Certain curious mental and nervous disorders incident to syphilis might resemble closely, but were not, neurasthenia. For the most part it was wrong to say that neurasthenia "drifted into" this, that, or the other morbid process, neurasthenia was not a general quality common to many diseases, but a particular process having its own causes and its own events The speaker referred to two cases diagnosed as neurasthenia in which necropsy revealed a cerebral tumour and a cerebral abscess respectively, both local diseases being evidently of a great many years' standing Loss of memory in hysteria was apt to occur in gaps with clean cut edges, in neurasthenia and insanity it was rather a general loss of tenacity Depression of spirits, when primary and persistent, suggested melancholia or hypochondriasis rather than neurasthenia or hysteria. The sadness of neurasthenia was the result of disappointment, in hysteria it was a reaction from excitement. Self seclusion was the note, not of neurasthenia or hysteria, but of melancholia or insanity of suspicion In insanity alteration of character, often seen first in letter writing, might put them on the right track The insane person was unaware of this disease or had but occasional glimpses of it, which was anything but the case in neurasthenia and hysteria, the hypochondriac, however, was prone to hug a delusion such as that of a snake or earwig in his body, he could not be convinced even by the demonstration of his own senses, and from this to delusional insanity was no far cry Of late years he had formed the opinion that neurasthenia was apt to follow the operations of surgery—sometimes even the smaller operations—if done under an anæsthetic The surgeon, satisfied with the local results of his operation, was apt to lose sight of this result. He believed it to be genuine neurasthenia and allied to that which followed some railway accidents They might inquire if this event had any affinity with post-operative insanity

In the discussion which followed the above,

Dr D **YELLOWLEES** (Glasgow) said that he agreed as to the importance of distinguishing neurasthenia, hysteria, and hypochondriasis from each other and from insanity He did not think, however that imperfect inhibition explained all the phenomena of neurasthenia, but agreed that it was necessary to distinguish neurasthenia from melancholia, as the lines of treatment necessary for these two affections were quite different. Seclusion and rest benefited neurasthenia but aggravated melancholia by favouring concentration of the patient s thoughts on himself. He thought that in cases of post-operative insanity there was an original underlying predisposition to mental breakdown and that the operation was only the exciting cause.

Mr C. S. MORRISON (Hereford) said that post-operative insanity in his experience, was invariably marked by acute tendencies to suicide In a case of this kind under his care treatment with warm baths, ample feeding and occasional doses of bromide and caffein produced an improvement of the physical and mental condition, while the impulse to self-destruction grew less and self control became greater Nevertheless, a tendency to melancholia persisted and the prognosis was uncertain.

Dr. FLETCHER BEACH (London) was of opinion that hereditary predisposition to insanity was a very important factor and that when it was present the symptoms of neurasthenia or hysteria which a patient exhibited passed eventually into actual insanity Many cases of neurasthenia recently observed by him had symptoms of dyspepsia and when the latter condition improved under proper treatment the neurasthenic condition also passed away apparently because the neurasthenia was in such cases of toxic origin.

Dr SEYMOUR TUKE (London) emphasised the fact that in neurasthenia the effect of sleep and rest was marked as regards the benefit obtained but the good effect was less in cases of insanity proper He agreed that the hypochondriac was nearer to the boundaries of insanity than the neurasthenic and thought that the treatment of many cases of hypochondriasis was a most dangerous thing to be undertaken by neurologists as such patients not infrequently attempted to commit suicide when affected with delusions of bodily disease.

Dr LLOYD ANDRIEZEN (London) stated that in the commonest type of neurasthenia, the cerebral, the lesion was a chronic nutritional debility of the cortical nerve-cells in general usually of congenital origin and life long duration It was manifested by states of cerebral fatigue readily induced and of undue persistence after ordinary work. Cephalalgia and cephalic and other paræsthesiæ were common Concentrated application and attention were difficult. It was different from ephemeral states of fatigue which in normal persons passed away with ordinary rest and sleep. True neurasthenia did not present the characteristic depression of melancholia, the exaltation of mania or of early paresis, the tendency to delusions of hypochondriasis and paranoia, or the intellectual enfeeblement of dementia præcox. While the neurasthenic might have fear of going mad he seldom or never developed madness. Hypochondriasis and hysteria major on the other hand, came nearer to the bounds of insanity and in particular to a group of the insanities which he had elsewhere described as paraphrenia. He alluded to a class of cases met with in practice but never in asylums and marked by simple depression of spirits occurring periodically or at regular intervals and continuing to do so throughout life without passing into melancholia proper or other forms of insanity One such case was cited where this was noted by him for 10 years in the case of a middle-aged man who confessed that he had suffered from such attacks since youth and Lange of Copenhagen had also recognised and described such cases. He referred to the diagnostic features separating neurasthenia from early general paralysis and pointed out that the neurasthenic, as distinct from the early paralytic, did not develop signs of intellectual and moral degeneration.

Sir JOHN SIBBALD (Edinburgh) regarded the subject of the relation of neurasthenia to the other neuroses and to insanity as of importance and felt it necessary to differentiate neurasthenia, which was a disease running a characteristic course from neurasthenic conditions and from incipient insanity

Dr HARRY CORNER (London) regarded neurasthenia as a disorder of the lowest psychical level and hysteria and hypochondriasis as affections of the higher psychical levels. This was borne out by the frequency of visceral and respiratory disturbances of a nervous character in neurasthenia, the respiratory disturbance taking the form of air hunger" and almost of asthma. Cardiac and circulatory disturbances and gastric dyspepsia with atony of the stomach and loss of appetite were also frequent in neurasthenia, while the presence of renal disturbance was shown by the passage of large quantities of pale urine The disturbances of hysteria lay in the higher mental spheres as shown by the emotional disturbances and the convulsions present. In hypochondriasis delusions referring to visceral organs were developed even in the absence of visceral disease, while visual and auditory disturbances were common.

Dr BEDFORD PIERCE (York) asked whether Professor Allbutt would include under neurasthenia cases due to toxæmia. He questioned whether the distinction between neurasthenia and insanity could be so clearly drawn as Professor Allbutt had done. He remembered cases of insanity which at one stage presented many symptoms of neurasthenia.

Dr ALEXANDER BRUCE (Edinburgh) agreed with the definition of neurasthenia given by Professor Allbutt, but wished to know whether there were not cases of partial or localised neurasthenia of the different viscera due to exhaustion of their nervous mechanisms.

Dr A. T SCHOFIELD (London) proposed the following definitions—viz. that neurasthenia was a general exhaustion of the nervous system preceded by a stage of irritation that hysteria was an affection of the subconscious mind producing results entirely apart from the will and consciousness of the patient that insanity was a disease of the conscious mind and that hypochondriasis occupied a borderland between hysteria and insanity being partly a disease of the subconscious mind and partly of the conscious mind.

Professor ALLBUTT then briefly replied, dwelling mainly on the distinctness of neurasthenia from insanity and referring to the diagnosis between neurasthenia, melancholia, and early general paralysis

Dr ROBERT JONES *read a paper on*

Apprehensiveness Stupor and Katatonia

In no form of mental disease, said he had greater difficulty been experienced as to the exact meaning of a term than in regard to the word katatonia which was first used by Kahlbaum in 1874 to designate a particular variety of insanity Continental authorities generally accepted Kahlbaum s views regarding the affection he described and recognised katatonia as a definite disease with characteristic symptoms running a special course Dr Jones however thought that katatonia was not a separate variety of insanity but was a symptom which occurred in the course of the cyclic forms of insanity It was rare after 30 years of age and was most frequent at about 20 years of age. It was more often met with among private than pauper patients and occurred more often in the brain worker than in the labouring man The essential feature was a tendency to the recurrence or repetition of motor and mental impulses followed by negativism—i.e. by a condition of passive resistance to every movement. It followed acute mania, melancholia, epilepsy or formed part of a cycle in periodic insanity The earliest stages of the affection were marked by irritability anxiety headache and painful feelings. Then followed a condition of marked apprehensiveness and painful mental prostration. Finally there developed a condition of muscular tonus with disinclination or inability for voluntary movement, the attitude being rigid and statuesque and the facial expression vacant and mask like. The patient in this condition took no notice of his surroundings his saliva dribbled down his chin he refused to take food and his urine was either retained or passed involuntarily Speech was absent and memory though present was indistinct and untrustworthy Occasionally meaningless words were uttered in parrot like fashion (echolalia) or meaningless gestures were made. When the resistive stage subsided there succeeded a cataleptoid condition with automatic movements of swaying singing or unintelligible utterances (verbigeration). The radial tension as measured by the sphygmograph was low and the circulation was feeble during the early and intermediate stages Occasionally outbreaks of violence occurred which were of momentary duration after which the patient subsided into a stuporous or cataleptic condition Occasionally self mutilation of the genitals was observed probably as the result of impulses arising from delusions. Excitement, however was rare in katatonia. As regards the terminations of the disease it was found that the greater number of katatonic cases became chronic and passed into mild dementia of an inert and sluggish type. Youth did not render prognosis more favourable, as many young persons passed into incurable dementia. Masturbation aggravated the malady Over strain and anxious responsibility rather than simple overwork were the exciting causes of this form of mental breakdown in adolescents and young adults of both sexes The pathological findings in post-mortem investigations were not sufficiently advanced or complete to enable them to correlate the symptoms during life with the lesions observed.

The PRESIDENT made a few appreciative remarks on the clinical interest of the paper contributed by Dr Jones and regretted that owing to want of time further discussion on it was impossible.

OPHTHALMOLOGY

THURSDAY, JULY 31ST

Dr ARTHUR W SANDFORD (Cork) opened a discussion on

The Treatment of Sclero keratitis

He believed this affection pure and simple to be an extremely rare one and that, with few exceptions, it was a local manifestation of acute rheumatism or of some more or less modified form of tuberculous infiltration and that it did not differ essentially from similar affection of other fibrous capsules, as of joints and testes, its importance in the eye consisted in the extension to episclera, iris, uveal tract, &c., whereby vision might be seriously diminished As a rule these complications had set in before treatment was applied for, which complicated matters A large proportion of cases occurred in adolescence in association with other scrofulous evidences and in females with menstrual irregularities, in adults it was rarely disassociated from constitutional rheumatism or gout. In those acute cases which were not tuberculous in origin he had found useful hypodermic injections of pilocarpine and dosing with salicylate of soda or aspirin, the eye being kept quite at rest, warm, and dry Iritic complications needed atropine but he felt this was to be avoided as much as possible. In scrofulous cases rest and warmth to the eye, doses of iodide of potassium with iodide of iron and tri iodide of caffein with a generous dietary, or the use of bichloride of mercury in small doses were useful even apart from specific taint. His experience of subconjunctival injections was not favourable, in some cases the reaction was severe and probably hurtful On subsidence of the affection the thinned sclera and opaque cornea had to be considered, for this long use of weak myotics and weak mercurial ointments and massage appeared to promote tissue change The results he felt were not thoroughly satisfactory since the affection was tedious and had a marked tendency to recur

Dr F E MADDOX (Bournemouth) said that the condition and its treatment were difficult and obscure, cases sometimes cleared up after treatment had been dropped. He thought that peritomy was of most general service, whilst yellow ointments and iodide of sodium lotions were sometimes useful Dry heat often gave good results and in this connexion he showed a mode of its application which he thought was more convenient than by the usual "muff warmer" His appliance consisted of a thin flannel disc in which was threaded a helical of fine tinned iron wire, the two ends of this were connected with a suitable electric current, it was light, small, cheap, could be placed within the usual dressings, and the heat could be regulated to a nicety by control of the electric current.

Dr HILL GRIFFITH (Manchester) divided his cases into two groups (1) where episclera was alone affected and (2) where all scleral tissues and even the ciliary body and vitreous were involved To these latter his attention had been particularly drawn and he regretted that he had never found anything to do real good, the cases just took their own way

Mr DEVEREUX MARSHALL (London) remarked upon the risk of using pilocarpine injections. Miotics tended to increase the local pain, and though they did perhaps tend to diminish corneal extension yet this did not compensate for the risk of blocked pupils

Mr CHARLES WRAY (London) thought that in extensions to the ciliary body atropine was called for, particularly in the ointment form

Mr W W GRIFFIN (Brighton) narrated cases which he had watched and the treatment adopted, he felt they were associated with a general lack of condition.

Mr BISHOP HARMAN (London) remarked on the use of adrenalin for such cases, there was without doubt temporary blanching of the eye to the great pleasure of the patient but the permanent result appeared to be *nil* In the case of an intelligent man who had run the whole gamut of treatments he had tried this drug, the man complained that it caused deep seated pain and cloudy vision, vision was found to be diminished and the field contracted, both were recovered a week or so later He thought that the use of the drug was not without danger, since there was theoretically the possibility of its producing some contraction of the retinal vessels and the same kind of anæmia of the retina as attended the use of large doses of quinine

Mr JOHN HERN (Darlington) was struck with the rather hopeless tone of the remarks as to treatment, he thought the constitutional condition underlay the local and must be sought out and treated.

Mr DEVEREUX MARSHALL asked Mr Bishop Harman whether he had noted any increase of tension with the use of adrenalin in the case which he narrated, he had noticed sudden increase following its use even to the suggestion of a glaucoma

Mr BISHOP HARMAN replied that in his case there had been no perceptible alteration of tension which throughout was normal.

Mr RICHARD CLEGG (Clayton-le Moors) noted the exacerbation of sclero keratitis with menstruation His most useful ally in combating the complaint locally was yellow ointment, beginning with low percentage and increasing steadily

Dr O E GLASCOTT (Manchester) also liked yellow ointment with on occasion belladonna, warmth and massage He emphasised the importance of correcting even trivial errors of refraction in such cases

Dr JOHN WIDMARK (Stockholm) demonstrated

Martin Janson's Siderophone for the Detection of Iron in the Eye

The electrical plan of the instrument consisted of two circuits, the primary having a dry cell, an interrupter and a coil, this last was placed at right angles to the centre of a coil in the secondary circuit, and induced currrents therein which were perceptible by sounds in a telephone receiver within the secondary circuit when the two halves of the secondary coil were not in electrical balance Suppose this balance to be exact the approximation of the coil to a particle of iron would disturb it, a nearness shown by sounds in the telephone The apparatus was undoubtedly very ingenious, simple, and handily set up, it had, however, to be proved whether or not it was sufficient to indicate the presence of very minute particles at a depth within the eye.

Mr CHARLES WRAY read a paper on

Civilisation and Eyesight

He said that it was generally believed that civilisation tended to produce myopia. This view had obtained credence, not from statistics, but because it appeared to be in harmony with the theory of evolution, yet it was far from clear that myopo genesis was due to adaptation True evolutionary "adaptation" emphasised the subordination of the individual to ancestry, but ordinary myopo-genesis subordinated ancestry to individual, and was compared with the undoubtedly true "adaptation" as rapid in the life of the species as post-operative astigmatism was in the life of the individual The principal difference between the two forms was due to the fact that such myopo genesis as that seen in schools was avoidable, and therefore a more or less voluntary condition, to determine this they required knowledge as to the frequency of each of the hypermetropic and myopic errors, excluding all blood relations to avoid bias. By a calculation based on a comparison of averages of many cases with the law of probabilities he showed that whilst one was able to estimate with great accuracy the number with each grade of hypermetropia up to 6 D, and approximately the right number of myopes, the myopia of the myopes was much greater than it should be. − 5 seemed to be nearly as common a refraction as − 2, and it ought only to occur once in 1759 cases, whereas it occurred in from 1 per cent. to 2 per cent − 4 and + 6 should be of equal frequency, and − 8 should be as frequent as + 10—i.e., it should occur once in some hundreds of thousands of cases As a matter of fact, a refraction of − 8 *and upwards* was met with in over 4 per cent of Mr Wray's cases If these results were accurate then civilised environment had had little effect on the hypermetropes, and causes that had failed to operate on them had operated on myopes, making their myopia much higher than it should be A striking feature of the results was the small number of persons with – 1 and – 2, especially when it was remembered that such diminution was necessary or the large percentage of cases with over – 2 D as found in verification would have been impossible. He noted that high myopia was not uncommon in children of tender years—i.e. in eyes that had not been exposed to close work—and found that it was a great exception for them not to have suffered from marasmus within the first five years of life but a myopic eye would seem to be a necessary antecedent.

Dr WIDMARK also read a paper on

The Ætiology of Myopia.

It was agreed, he said that eye strain during adolescence was a decisive cause, but not as to the producing factor of the visual act. Of the three factors, accommodation convergence and retinal perception, the first two had received great attention, he felt to the neglect of the last. Opacities of the cornea and astigmatism of one eye tended to throw excessive and short-distanced work on the sound eye and within his experience this sound eye was the earlier affected with myopia. Excessive convergence he thought disproved by the fact (1) that in these cases the poor eye took little part in vision (2) that after the excision of one eye in children myopia might occur in the other and (3) of the liability to divergent strabismus in myopia, for each of these statements he gave evidence of many cases He further combated the opinion as to the causative influence of excessive convergence by a series of observations which went to show that no excess was present or possible with the majority of his myopes, also by the fact that staphyloma did not occur at the point where excessive strain on the globe should fall did the traction of the optic nerves become serious. He thought that the great use of the eyes such as reading demanded tended to cause a hyperæmia in the bottom of the eye, allowing of softening and subsequent stretching of the coats. These factors would be particularly powerful where from defect of one eye greater work was thrown on the other or sounder eye

In the discussion of the two papers which followed Dr MADDOX objected to the exclusion from count of blood relations he thereby directly diminished the influence of heredity He thought the calculation showed very clearly that high myopes arose from low myopes rather than hypermetropes

Lieutenant-Colonel DRAKE-BROOKMAN said that in 1867 on his first experience of eye work in India, he noted but few cases of myopia since then with the increase in native schools, it had become quite extensive.

Dr GRIFFITH expressed his disbelief in the prevalent idea that hypermetropes might become myopes. He had never had such a case under his notice, but he quite agreed that high myopes were produced from low myopes

Mr DOYNE was astonished at the statements of the last speaker it was to him a matter of common observation that hypermetropia did sometimes diminish even to the production of myopia.

Mr J B STORY (Dublin) also agreed in the occasional change of hypermetropia to myopia he also controverted Lieutenant-Colonel Drake Brookman's deductions from Indian experiences. He felt the cases had existed but had not applied for relief The majority of his high myopes came from the West of Ireland from among folk not of the highest intellectual ardour and amongst whom the bad influences of civilisation had little effect.

Dr MCGILLIVRAY expressed his surprise at some remarks made he certainly had noted cases of hypermetropia turning to myopia where the use of atropine effectually excluded error one case he certainly remembered where an error of +2 D became –3 D further high plus errors were common in young people but rare in adults How came the diminution? Certainly not merely by increased density of media.

Mr HOLMES SPICER also had seen such changes but the degree of change had not within his remembrance been greater than from 2 to 3 D He thought Dr Widmark's paper of great interest still he felt convinced of the truth of the convergence theory of increase of myopia, at any rate it was too good a working hypothesis to be dropped easily He felt that Dr Widmark's ideas must first be tested on a wider range of cases

Exhibition of Cases

Dr DAVID MCKEOWN (Manchester) showed two cases 1. A case of Double Congenitally Displaced Transparent Lens treated by Discission The patient was a male aged 20 years. He had always had very bad vision both far and near Glasses were of no use the lenses were displaced upwards and their edges crossed the pupillary area. Both eyes had been operated upon, in the left the lens had become opaque and in the right it had been absorbed, so in each case a single refractive series replaced the former double series. The results were excellent. The man now did better work and obtained higher wages 2. A case of Chronic Ulcer of the Cornea in a women aged 60 years. It had existed 23 months and was not healed yet, it commenced after an attack of influenza, without apparent immediate cause He thought it was a case of damage to the fifth nerve succeeding influenza.

LARYNGOLOGY

WEDNESDAY, JULY 30TH

Professor GUSTAV KILLIAN (Freiburg) opened a discussion on

The Diagnosis and Treatment of Foreign Bodies in the Upper Air-passages and Gullet.

He said that his special part of the subject was to draw attention to the direct methods of examination which were based upon the recognition of the fact that it was possible to penetrate in a straight line with instruments into the air passages and œsophagus without damaging these organs In the case of the œsophagus the œsophageal probe with olive-shaped end and skiagraphy did not always give trustworthy diagnostic results. The olive passed along the posterior wall of the gullet In case a foreign body was impacted in the anterior wall it might pass it without coming in contact with it In the Roentgen gram the shadow of a foreign body in the gullet might be hidden by the shadow of the vertebral column or the heart and many foreign substances gave no shadow at all Direct œsophagoscopy was the only absolutely trustworthy method Kussmaul attempted this in the year 1868 von Mikulicz, von Hacker Rosenheim and others succeeded in developing and completing this method. It might be employed in most patients by practised hands as a rule local anæsthesia with cocaine was sufficient, in excitable patients and in children general narcosis was necessary By means of œsophagoscopy the gullet might be systematically searched from above downwards, it was possible to recognise the exact place and form of the foreign body its shape its position and its relation to the gullet wall and to see whether the latter was inflamed or had been injured by previous vain attempts at removal or pushing forward the foreign body Thus œsophagoscopy would show everything that might be of importance for the purpose of the removal of a foreign body and it would further allow an attempt at extraction under the strict supervision of the eyes The most suitable instruments for extraction were those in the shape of slender forceps by careful traction or eventually by moving and turning the foreign body was freed and then removed slowly either through the œsophagoscope or if too large, together with the latter instrument. This method was of special value for the extraction of foreign bodies in cases of stricture of the œsophagus where particles of food had become impacted and patients had thus been spared from undergoing œsophagotomy and gastrostomy If the foreign body was large, had sharp edges points, or hooks, as for instance, dental plates all attempts at extraction were dangerous, these might easily lead to fatal injuries of the gullet In such cases œsophagotomy was indicated if the foreign body was situated no deeper than from 24 to 26 centimetres from the upper incisors, if deeper gastrotomy or posterior mediastinotomy was called for An exception might be made in the case of vulcanite plates without large metallic parts. Professor Killian succeeded in cutting such a plate (which was fixed at a depth of 35 centimetres) into pieces by means of a galvano-cautery snare, and in removing it piecemeal In cases in which one had been able to see that the wall of the œsophagus had been deeply injured extraction should not be attempted. Early œsophagotomy was here required and it was easier to locate the injured part whilst the foreign body was still fixed The same principle which lay at the foundation of œsophagoscopy had within recent times also been applied to the trachea and bronchi. One was able to make an inspection right down into the lungs by the introduction of straight tubes into the trachea and bronchi a fact most important for finding and removing foreign bodies. Professor Killian called that he did not wish to detract from the merits of ordinary or indirect laryngoscopy (by means of the laryngeal mirror) This had had triumphs in the diagnosis and removal of foreign bodies from the larynx, but just in those cases in which foreign bodies most frequently occurred—namely, in children—insurmountable difficulties often arose. In these cases direct laryngoscopy (Kirstein's autoscopy) could always be successfully employed, especially after administration of an anæsthetic, and the patient's head being in a dependent position Of course, if there was much dyspnœa a preliminary tracheotomy must be performed. He had thus been able to remove from the larynx of a child a tightly fixed collar stud which would otherwise have required a thyrotomy This method was of even greater use in the case of impaction of foreign bodies in the trachea, as ordinary laryngoscopy frequently failed Pressure on the base of the tongue or the laryngeal surface of the epiglottis with one of the different spatulas designed by Kirstein might suffice to give, even in young children, a view into the trachea. But Professor Killian preferred to employ direct upper tracheoscopy, using a straight tube of sufficient length and of a width small enough to get through the rima glottidis He was thus entirely independent of any disturbing reflex action of the pharynx or larynx In the adult local anæsthesia with a 25 per cent. alcoholic solution of cocaine was nearly always sufficient, but a preliminary injection of morphine in addition was a great help In children it was best to give chloroform, the head hanging over the edge of the table He preferred not to use a "mandrin" or the finger as a guide, but he introduced the instrument without "mandrin" under the guidance of the eye, looking continuously through the tube and finding his way gradually through the pharynx and larynx into the trachea Foreign bodies were thus easily discovered and extracted If freely moveable they were apt to be blown against the lower end of the tube and might thus produce attacks of suffocation, by pressing the foreign body back respiration was at once made free again If tracheotomy had been necessary and the foreign body had not been coughed up, a short tube might be introduced through the tracheotomy wound into the cocainised trachea—lower direct tracheotomy, a method employed by Pieniaczek. Aspirated foreign bodies were specially apt to become fixed in the bronchi If only just beyond the bifurcation, upper or lower direct tracheoscopy was all that was necessary for diagnosis and extraction. If deeper down he employed tubes of greater length which he introduced into the cocainised bronchi. The bronchi, which were highly elastic tubes imbedded in soft tissue, might without fear be pressed into the median line and the trachea, larger bronchus, and branch might thus be brought into one straight line Thus out of the upper and lower tracheoscopy his methods of upper and lower bronchoscopy were evolved Bronchoscopy allowed the whole bronchial tree to be searched. Though the left principal bronchus branched off at a sharper lateral angle it was through gentle pressure brought almost as easily into view as the right The view had to be kept clear by sponging the secretion away or by sucking it up by means of a small pump designed by Professer Killian For all these methods of examination illumination was best made by Kirstein's forehead lamp, for demonstrating purposes Kaspar's handlé was most useful. The foreign body could thus in most cases be found or its absence proved with certainty One contingency had to be kept in mind If a tube was introduced into a principal bronchus which was entirely stopped up by a foreign body respiratory difficulties would at once occur, as air would not pass in large enough quantity into the other healthy lung at the side of the tube, in such circumstances the tube introduced should have a lateral opening at some distance from its lower end. For the removal of foreign bodies from the bronchi a good view, great care, and quietness in procedure were essential Slender tubular forceps, blunt booklets (especially in the form of the well-known Lister's hook), were the instruments of most use. Their manipulation at so great a depth was not an easy matter but might be learned and practised on a phantom Hitherto bronchoscopy had been employed in 20 cases Of these 11 were under Professor Killian's care. Nearly one half of all the patients were children (six aged between two and six years and four at ages from eight to 12 years) The foreign bodies were of the most varied character, they had in one half of the cases been inhaled a few days before, in the other half they had been in the lung for months or years. In nine out of the 11 cases in which upper bronchoscopy was employed it led to certainty of diagnosis In two cases it failed—in one, because the foreign bodies, small feathers as fine as down, were too small, and situated too far towards the periphery, they there coughed up afterwards In the other case, a large pin with a glass head aspirated 10 years previously, had become imbedded peripherally into what was probably fibrous tissue In all the nine cases in which lower bronchoscopy was employed it established the diagnosis. Twice it could be proved with certainty that the suspicion of a foreign body in the lung was unfounded. Extraction was attempted in 15 cases, and succeeded eight times with upper, and five times with lower, bronchoscopy, in two cases recorded by Thost (Hamburg) and Spiess (Frankfort) it was unsuccessful—in one case owing to the want of suitable instruments and in the other because the foreign body lay in an abscess cavity with a narrow opening Both these patients died Of the patients in whom extraction was successful only one died, and that nine months later, from purulent pleurisy of the healthy side Considerable stenosis had occurred at the place where the foreign body—a collar stud—had been lying for five months in the left principal bronchus Extensive bronchiectasis had undermined the larger part of the atelectatic lung tissue, which also had undergone extensive fibrous degeneration Two cases in which the foreign body had remained in the lung for a long time were considerably improved as far as the lung trouble was concerned All the other patients were permanently cured, the severe and acute lung symptoms disappearing rapidly Professor Killian gave the facts of some of the more specially interesting cases which showed that within a comparatively short time bronchoscopy had given a rich percentage of successes (Practical demonstrations were given by Professor Killian of his methods of bronchoscopy and œsophagoscopy)

Dr JOHN MACINTYRE (Glasgow), in his opening speech, dealt with the progress made in the examination of the upper air passages and the œsophagus by means of illuminative and radiant matter He considered that the value of the x rays had not been fully appreciated, for not only could foreign bodies be detected by means of them but the tissues also could be differentiated Dr Macintyre gave a lantern demonstration of the apparatus and the methods he used for investigating by means of the x rays cases of foreign bodies in the upper air-passages and œsophagus Photographs of a powerful magnet used for extracting foreign bodies were demonstrated on the screen A series of radiograms was also shown illustrating the positions occupied by foreign bodies

Dr J WALKER DOWNIE (Glasgow) continued the discussion and gave a lantern demonstration of a large variety of foreign bodies which he had recovered from the upper air passages

Mr W THELWALL THOMAS (Liverpool) spoke of the superiority of the metal ended probang over other probangs for sounding and of the metal ended black bristle probang for the extraction of foreign bodies in the œsophagus. The œsophageal bougie he considered to be only of service in the diagnosis of foreign bodies.

Dr R O WILD (Zürich) thought that Dr Macintyre's suggestion of using a powerful magnet in the region of the thorax for the extraction of foreign bodies might be attended with danger

PHARMACOLOGY

THURSDAY JULY 31ST

Dr RALPH STOCKMAN (Glasgow) opened a discussion on

The Therapeutic Value of Arsenic and the Justification of its Continued Use in the Light of Recent Observations concerning its Toxic Action

After Dr Stockman had eulogised the acumen of the members of the medical profession in Manchester in connexion with the late epidemic of arsenical poisoning he proceeded to point out that poisonous effects very seldom followed the exhibition of arsenic in appropriate doses of the official preparations The recent epidemic to which he had referred had demonstrated that many persons were constitutionally unable to resist the influence of poison in arsenical beer The eyes of the profession had been opened to the extreme danger to the nervous system of overdoses of arsenic. Dr Stockman showed that whilst alcohol did not cause pigmentation it might produce peripheral neuritis and that arsenical alcohol was liable to produce both those symptoms

Dr M **Pope** then spoke from the point of view of arsenic in the treatment of chorea. In his opinion the recent wholesale poisoning by arsenical beer might result in neglect of such a valuable remedy as arsenic. It had to be admitted, of course, that some cases were obviously unsuited for treatment with the drug

Professor R. B. **Wild** (Manchester) drew attention to the fact that his notes of the arsenical beer epidemic of Manchester showed that women were much less tolerant of arsenic than men. What he was astonished at was not the number of people affected by the poison but the number of people who escaped any evil consequences

Dr A. P **Luff** (London) expressed the view that the epidemic should be the means of inducing medical men to take heed in regard to any of their patients showing an intolerance of arsenic.

Dr. F W **Tunnicliffe** (London) urged that until more complete investigation had been undertaken the opinion should not be positively stated that very small doses of arsenic produced the intense symptoms that had been described

Dr. E. S **Reynolds** (Manchester) next spoke and emphasised the point that the dose of arsenic in arsenical beer was greater than had been reported. One result of the recent epidemic was that they had learnt that in analysing for arsenic a certain proportion remained in the apparatus. It had been estimated that in one gallon of beer containing arsenic the amount of the poison was from one and a half to two grains.

FRIDAY AUGUST 1ST

The **President** (Dr **Nestor Tirard** of London) dealt with the subject of

The Local and General Treatment of Diphtheria

He thought that since the introduction of antitoxin in 1890 the experience of the last 12 years had fully shown its value From 1891 to 1896 the new method of treatment appeared to establish its claim on the attention of the medical profession but from 1895 when the medical superintendents of the Metropolitan Asylums Board hospitals issued their special report and from 1898 when the Clinical Society issued a report upon the clinical value of antitoxin in diphtheria, the whole question appeared to him to be settled It was true that during these years the treatment had been continually assailed and notwithstanding the reduction in the mortality which appeared to have been undoubted many ill effects had been attributed to the use of antitoxin. It was perhaps only necessary to remind them of the greater frequency of paralytic conditions and of albuminuria and also of the production of rashes of various types all of which were laid to the credit, or rather to the discredit, of antitoxin. Many of the attacks appeared to be based upon sentimental grounds, some upon a conservative antagonism to new forms of treatment. In 1897 he ventured to write a small book on the subject of diphtheria and antitoxin in which he detailed his experiences and he thought that as an unwilling convert his experiences would receive attention Attention was certainly roused, for immediately after the publication of the book he received an anonymous letter which was so precious that he ventured to introduce it there. Has Mr Nestor Tirard noticed a paragraph in the *Cable* in which it is stated as a fact that the juice of a pineapple will cut the diphtheria membrane when nothing else will? Why not try this and discard the disgusting and cruel antixonial (*sic*) treatment? All these systems allied to vivisection are wrong Has Mr Tirard read what is written in the Bible about doing evil that good may come? It is written Their damnation is just And spiritual clairvoyants say that the fate of vivisectionists beyond for a long period is too awful. So long as such practices are tolerated the hospitals will never get sufficient money as the bulk of the populace and all right-thinking men and women are against it. From an Influential Person." This letter was of extreme interest as indicating the attitude of many earnest but prejudiced persons. Still in the interval he had thought that the numerous reports on increasing experience with antitoxin had carried conviction to the medical profession at least until the appearance of the recent correspondence relating to diphtheria and its treatment at Colchester in which the use of antitoxin in diphtheria was termed bowing the knee to medicinal Baal." The whole question therefore, appeared to be re-opened and ripe for discussion. He did not propose to weary them with statistical proofs Those were to be found in the reports before mentioned and would prove interesting reading The points he wished to raise were briefly these (1) whether any remedy or remedies gave the same sense of security and of hope that were derived from the use of antitoxin (2) whether the ill effects attributed to antitoxin were not rather sequelæ of the disease, their greater frequency being due to the fact that since the use of antitoxin so many more patients lived to experience such sequelæ (3) whether the disease even in its milder form could be safely treated by any local or general measures and (4) whether after the use of antitoxin greater security was obtained in laryngeal cases by the use of intubation or by the performance of tracheotomy Incidentally he would wish to draw attention to the very different rates of mortality which occurred with nasal and post-nasal cases as compared with pharyngeal cases and he would also like to draw attention to the diminished frequency of laryngeal diphtheria since the employment of antitoxin. During many years in the wards of a children's hospital in London he had seen many so called specifics tried. Most of these were of the nature of antiseptics. Of the local measures he might perhaps mention lactic acid boric acid, perchloride of mercury biniodide of mercury sulphurous acid and paraffin. Some of these were directly applied to the membrane on a swab of cotton wool. Others were used in the form of spray It had further to be noted that sometimes the membrane was carefully detached before the application of the remedy although that method of treatment was speedily discarded, as the membrane almost invariably spread more rapidly owing to the production of a raw surface. For all of those remedies good results were claimed in individual cases, and although many proved rebellious to *any of these forms of treatment the mental attitude of* dealing with diphtheria was as follows If the case was seen early and the membrane was confined to the soft palate and fauces and did not spread rapidly they became somewhat sanguine. On the other hand if laryngeal dyspnœa arose as evidenced by increased rapidity of breathing and marked retraction of the costal margins, they might be obliged to perform tracheotomy and in many epidemics this operation merely seemed to render death less painful It must be admitted that from time to time long lists of consecutive cases in which tracheotomy had been performed successfully were produced by the medical officers but these brilliant results could not always be counted upon and were indeed sometimes viewed with some suspicion. Since the introduction of antitoxin they had been far more hopeful. When the case was seen sufficiently early and the remedy immediately applied the frequency of laryngeal diphtheria was much diminished although unhappily in poor districts children were often brought to the hospital when the aspect of the case was extremely grave. Still, although in a general hospital the selection of cases was distinctly against them—since all who were well enough to undertake the journey without danger were sent to the nearest fever hospital—yet their results continued to afford satisfaction and as he had commenced by saying he thought that one of the chief points to be considered was the relative advantage of intubation and of tracheotomy That question according to his observation appeared to be determined largely by the manual dexterity of the medical officers. Some appeared to find a difficulty in inserting the intubation tube. They scarcely seemed to realise the alteration in the direction of the tube which resulted from any slight change in the position of the hand of the operator and accordingly with some he had no doubt that the child was in a condition of greater safety if operated upon by the method which was easiest to the operator On the other hand, he must express his personal preference for the use of intubation rather than of tracheotomy They had all probably noted the rapidity with which the membrane in diphtheria liquefied and disappeared after the use of antitoxin. They were frequently able to remove the intubation tube within 24 or 48 hours of its first introduction. On the other hand when tracheotomy had been performed it was often difficult to remove the tube as early since in many instances the child felt a nervous dread of the removal of the tube and ceased to breathe Sometimes however that arrested respiration was undoubtedly due to changes in the positions of the cords or due to agglutination of their margins. He had witnessed several cases in which after tracheotomy in diphtheria the child had been doomed to employ a tracheotomy tube for some years, and his impression was that possibly in some of those cases the trouble was due to keeping the tube in too long and that it would *not* have arisen had intubation been performed

---

INDUSTRIAL HYGIENE AND DISEASES OF OCCUPATION

WEDNESDAY, JULY 30TH

Dr S KING ALCOCK (Burslem) read a paper opening a discussion on

The Value of Systematic Examination of Workers in Dangerous Trades

He said that it might be assumed that the official aim in instituting these examinations was (1) elimination of the unfit, (2) early recognition of dangerous symptoms and consequent diminution in the amount and character of trade diseases, (3) improvements in the treatment of lesions in certain trades (e.g, bi chromate), and (4) accumulation of statistics In actual practice the following results were being secured (1) gradual elimination of the unfit (whether from inherent debility or from illness produced by occupation), (2) better standard of hygiene, consequent on repeated warnings, &c., and (3) accumulation of valuable statistics concerning the original and acquired characteristics of workers—e g, age limit, relation between pregnancies and miscarriages, order of development of symptoms of poisoning, &c There were limitations in the amount of accurate information obtainable. The ordinary medical inquiry into the state of a patient comprehended a pertinent questioning and an unimpeded physical investigation, but the industrial examination was *sui generis* and had little in common with the conditions obtaining in private or hospital practice, it compared more closely with the examination of a candidate for life assurance, as in both cases the truth might only be elicited with difficulty and with little voluntary co-operation from the examinee. Consequently there was a limit of accuracy as the verdict depended on the report received from the worker (who often suppressed inconvenient truths) added to facts brought out by the incomplete physical examination. A well lighted room affording privacy for each examination was essential. Notes put in a factory register necessarily could not be full, many details could not possibly be inserted. Therefore it was wise to keep a private note book. The general type, facies, pallor, speech, tongue, tremor in outstretched hand, grasp, and resistance to forcible flexion of wrist, should be noticed If strabismus was present it should be noted whether it was of old standing or recent, and if ocular troubles seemed imminent optic neuritis should be examined for In deciding on suspension or rejection the personal element in judgment was necessarily involved, and a plan that he had found very satisfactory in practice was to classify the cases according to the degree of severity Slight colic, pure and simple, of short duration, female anæmia in adolescence, aggravated by employment Moderate colic with anæmia, advanced anæmia, apparently uncomplicated, slight muscular paresis Severe advanced paralysis, encephalopathies In estimating possible causes, after reviewing them as producible apart from industrial poisoning it was well to remember the value of associated symptoms, each of which taken separately had little pathogenic significance It was well to suspend or to reject young persons of either sex for slight reasons, but to act more cautiously in the case of the bread winner of a family Warnings instead of actual suspension were often useful and persistent threats and an inquisitorial style of examination were often effective. The periodical examinations were just as necessary now, notwithstanding the general regulations governing work in factories, because no restrictions could keep the careless worker free from danger Cases of poisoning of a slight and doubtful type were always in evidence, while the reports of independent practitioners had shown that there were still sections of employment as yet unscheduled which should be included as dangerous, so that their addition to the schedule must follow

Mr B M BOND (Poole) contributed a paper which was read by the Secretary In it Mr. Bond stated that in his district the examination of women and young persons who worked in dangerous trades had been carried out every month for nearly four years The chief value of the examination, in his opinion, lay in the power possessed by the surgeon to suspend or to discharge female workers injuriously affected by their work. The only toxic substance with which he had to deal was lead and his workers were majolica painters and colour dusters The two states of the worker obviously most in need of supervision were pregnancy and anæmia. He believed anæmia to be the most dangerous factor in female workers He thought that colic and gastro intestinal troubles generally were the prerogatives of the house painter for the most part Starting with a diminished number of red blood cells, and corresponding enfeeblement of oxygenation, the influence of the lead on the blood-cells actually present was entirely pernicious, the blood became more watery, the red cells were reduced below their (already) low standard, and the end came with startling suddenness It was a matter of great difficulty in localities where anæmia was prevalent to distinguish anæmia *a loco* from anæmia *a plumbo* Certain individuals were highly susceptible to the influence of lead, and in some cases this influence was not demonstrated by any obvious sign or "signal symptom," until they suddenly became unconscious and died. The lead line on the gums was often conspicuous by its absence To suspend a girl from her work because she was anæmic might be unfair to one who had always been anæmic, and the gradual increase of pallor, without the blue line, headache, colic, or peripheral neuritis, was extremely difficult to gauge The cases of girls with fresh complexions who became sallow, heavy, and cachectic at their work were clear, but the fatal cases that had occurred in his experience had been of a nature that nothing short of a periodic blood count could have foreseen. The pathology of plumbism was still undetermined He had for some time held the opinion that in the great majority of cases lead entered by the digestive system and was in most cases inhaled by the mouth and absorbed by the oral and pharyngeal mucous membranes, in addition to being swallowed dissolved in saliva. The action of the lead after its entrance into the system was also a matter of great difference of opinion. It was difficult to exclude the blood in any case, as the lead must be carried to an organ before the latter could be injuriously affected. He thought that in all cases of lead-poisoning the blood was primarily affected and that in cases of saturnine encephalopathy it was the only part affected. With regard to prophylaxis much might, of course, be done The daily ingestion of sulphur—in dose proportionate to the work—could be strongly impressed on the minds of the workers. The worker in lead must be surveyed as an individual and idiosyncrasies must be carefully studied and allowed for—the "personal equation" was of vital moment. The soil on which she lived, the climate in which she dwelt, must be taken into account. The swing of the pendulum in its monthly excursions must be carefully estimated and corrected. The *nuances* of energy and vitality, of buoyant vigour and alertness, must be weighed or compared, the increase of pallor or the reverse must be clearly stamped on the observer's mind, in short, the whole aspect of the worker must be closely scrutinised

Mr W H. VICKERY (Newcastle on Tyne) thought that every worker in lead absorbed a certain amount, and it was the duty of the inspecting surgeon to try to determine at what point this absorption passed the boundary line of safety The main signs which the text books laid stress on were the blue line on the gums and the appearance of muscular weakness in the extensor muscles of the hand and wrist, but it was difficult to appraise either of these at their correct value. The blue line varied in the rapidity of its onset and on its intensity according to the condition of the mouth and teeth. A worker with a number of carious teeth and who never used a tooth-brush rapidly acquired it, while one suffering from severe lead colic who had a complete set of false teeth showed no blue line at all The presence of muscular weakness was always difficult to determine. Some men naturally had greater power of wrist extension than others and in the usual method of examination could extend their wrists well, even some time after the trouble had started, and since some of the inspectors had been in the habit of trying the power of extension in the men the men had taken some trouble to develop their extensors to prevent being suspended from this cause. The most trustworthy sign, generally speaking, was progressive anæmia. It was a safer guide than any other sign, because the worker had no way of counteracting it

Dr W A. ATKINSON (Camberwell) remarked that his experience in the systematic medical examination of workers employed in the enamelling of metal plates, where lead was one of the chief ingredients of the enamelling powder dated from July 1897 since which period he had visited an enamelling firm in the factory district of Camberwell once a month and had carefully examined the men employed there. He considered that the periodical examination of lead workers was undoubtedly a safeguard against plumbism because it gave an opportunity of detecting some of the earlier symptoms such as anorexia and constipation, and such cases, if taken away from the influence of lead and placed under appropriate medical treatment seldom developed the more marked symptoms of lead poisoning

Dr J HOLMES (Radcliffe) said that at the tile works from which his experience was drawn and which extended over seven years good results had followed systematic examination In his opinion the blue line was misleading for it depended in a large measure on the presence or absence of tartar on the teeth.

Dr T F YOUNG (Liverpool) said in reference to phosphorus poisoning that anæmia was a pronounced symptom and he was quite convinced that in trades involving the use of lead or phosphorus constant supervision and examination were very necessary

Dr THOMAS OLIVER (Newcastle-on-Tyne) in his paper stated that no doubt existed in his mind as to the benefits that accrued from a systematic medical examination of workers engaged in dangerous trades, and by that he meant an examination repeated at regular intervals. Although often extremely easy it was nevertheless sometimes very difficult, especially in the early stages to detect the signs and symptoms of lead poisoning However valuable as a confirmative sign of plumbism the presence of a blue line on the gums might be this must not be regarded as a proof that at the time of its detection the worker was suffering from lead poisoning One of the earliest *signs or symptoms of plumbism was slight alteration* in the complexion of the worker with complaint of a metallic taste in the mouth and diminished zest for food. As a rule there was something in the general aspect of the worker that informed the medical examiner of a man or woman becoming slowly poisoned. The ability to recognise this change was personal to the examiner himself It was the man or woman who was being poisoned that should be considered by the medical man and not simply signs of lead poisoning looked for Lead often acted so slowly and insidiously that its effects were only very gradually produced. In many instances it was but a very small line that divided the ordinary workaday health of the white lead worker from the fully-developed plumbism of the hospital in patient. One or two days additional employment in the factory and a female worker who was just on the verge of breaking down at the time of inspection was without further warning precipitated into the worst form of plumbism—viz. lead encephalopathy—in which she died or recovered but with her eyesight lost. There was a form of plumbism that developed with a suddenness almost akin to an explosion, and yet in such a case if careful inquiry had been previously made there might have been detected some premonitory symptoms Such cases appeared every now and then in works notwithstanding systematic medical examination and their occurrence must not be used as an argument against the necessity of the examination but as a reason for the exercise of greater care and discrimination. In females working in lead processes the development of hysteria without any of the ordinary assignable causes would probably point to lead intoxication and in pregnant lead workers the recurrence of abortion or repeated miscarriage of a dead fœtus, while the mother herself remained healthy would indicate the probability of saturnine poisoning Systematic medical examination of the workers was also beneficial to the employers By saving the breaking-down in health of large numbers of the workpeople a particular trade lost the bad name it had made for itself with the public and employés were more easily obtained. Employers objected to the examination on account of temporary dislocation of the work and of the expense, but so far as expense was concerned that should be one a tax upon the finished product. Apart from the irksomeness and their dislike of the examination as an examination what the workpeople objected to was the compulsory suspension from work with the loss of wages which this entailed. At present there were signs in one industry of how that might be overcome The Staffordshire potters had recently agreed to compensate workers in lead processes who were laid aside through plumbism. They had undertaken to provide gratuitous compensation after the third week of suspension the amount to be one-half of the wages on an average of the 13 weeks previously and to continue this during incapacity from work for a year on the testimony of a medical certificate also where death occurred within six months of suspension a year's wages would be paid to the dependents In order that any working potter should receive those benefits he must submit to the monthly medical examination and have been in a works or working in lead processes for 13 weeks before becoming ill. Workers could be protected by (1) improved ventilation of factories and removal of dust—the removal of dust was most important for it was generally admitted that the dangers of lead poisoning were greatest when the metal entered the system by respiration, (2) wearing of respirators (3) alternation of employment (4) good food, (5) systematic medical examination—the moral effect of which was to make the workpeople more careful than they otherwise would be and (6) suspension and medicinal treatment.

Dr A. SCOTT (Glasgow) thought that no person, old or young should be employed in a dangerous trade without a medical certificate of fitness and that in addition to the usual monthly examination at the factory the certifying surgeon should have the power if necessary of visiting and examining absentees at their homes, while in industries in which there was danger of poisoning from lead mercury arsenic, phosphorus, or anthrax every case of illness however trifling should be reported to the certifying surgeon in order that the disease might be early diagnosed and treated with greater hope of success

Mr COLL. CAMPBELL (Saddleworth) said that the blue line if present was an admirable aid to diagnosis but it might not be present in a large number of cases.

Dr T M. LEGGE (London) said he agreed with the suggestion that all cases of illness that were found in factories should be followed up in their homes

Mr J KEAY also joined in the discussion.

The PRESIDENT of the Section (Dr WHITELEGGE, C.B.) said that the results obtained from statistics and the information gained that morning could not but lead them to the conclusion that success so marked in the past ought to be extended to a wider field.

Mr W F DEARDEN (Manchester) *after alluding generally* to the poisonous effects produced by substances derived from coal tar on the health of those engaged in their manufacture and application stated that although extensive investigations had been made in this respect in connexion with their manufacture and their employment in the production of explosives, little attention had hitherto been given to their effect on the workers in dye works and print works He himself had observed among dyers of fast aniline blacks similar ill effects to those described in connexion with the other processes alluded to. In 1863 Lightfoot of Accrington patented a process of producing aniline black Although this colour had been known for so long a period the high price of aniline and the difficulties encountered in obtaining a good and reliable shade without affecting the goods had up to about 12 years ago been adverse to its extensive application. These drawbacks had now been removed with the result that the production of aniline black had become one of the commonest operations in dye and print works Though each firm had its own particular process the principle involved in all of them was the same—viz a rapid oxidation of the aniline in presence of the fibre In making the dyeing solution some dyers used aniline salt and others aniline oil The latter being volatile got into the surrounding atmosphere by the heat evolved when it was being mixed with the hydrochloric acid and could thus exert ill effects through inhalation. Poisonous effects might also result from the oil or a solution of the salt *coming into contact* with and being absorbed by the skin This frequently took place through the practice of running the cloth through the hands when saturated with the dyeing solution. In the ageing process which followed the saturation of the cloth with the dyeing solution the material was subjected to a high temperature so that in case of bad ventilation or of workpeople entering the ageing chamber cases of poisoning were likely to occur It also sometimes happened that the aniline oil contained *nitro-benzol as an impurity and it* should be borne in mind that this substance was very similar to aniline in its toxic effects The symptoms exhibited among the class of workers referred to were sickness loss of appetite, weariness pale countenance ulcers of the lips and finger nails, and, in extreme cases, unconsciousness People were, however, not all affected alike, some being quite resistant to ill effects whilst others rapidly succumbed. Full credit was due to the dyeing trade for improvements that had already been carried out with a view to obviate ill effects, but the fact of a well-known poison being extensively used in an ordinary trade process, with known injurious results in the absence of proper precautions, showed the desirability of establishing some supervision Among the precautions that he advocated were the use of aniline salt in place of oil, or if oil be used the provision of a suitable hood or other contrivance over the mixing vessel to carry off the noxious fumes , the boxing off of the drying cylinders , the provision of the suitable respirators for anyone entering the ager , the adoption of means to prevent the workpeople handling the cloth when saturated with the dyeing solution , and plenty of air space and efficient ventilation

ETHICS

THURSDAY, JULY 31ST

Mr O S LOCH, secretary of the Charitable Organisation Society, opened a discussion on

Hospital Reform

by reading a paper on the Better Organisation of Medical Relief He commenced by quoting what the late Mr Sampson Gamgee of Birmingham had said on hospital abuse some 20 years ago, showing how these remarks still applied in the present day Mr Gamgee had maintained that the bad out-patient department work "lowers medicine in practice to the mere act of administering physic in all cases, to the neglect of full inquiry into the cause of disease, and of well considered advice for restoration to health in conformity with the laws of nature " The number of out patients attending the 92 London hospitals had increased from 1,082,259 in 1887 to 1,448,026 in 1897, and to 1,584,987 in 1900 The number of in patients had likewise increased, but there had been no augmentation in the number of medical attendants, the hospital staffs being approximately the same. This was as bad for the patients as for the profession. In 1899 inquiry had been made General practitioners in different parts of London were questioned One of them who had attended at the out-patient department of a London hospital for two years thought that the majority of patients would recover more quickly if attended in their own homes, adding that "cases of bronchitis and whooping-cough, which form no small proportion of the out-patient cases at a children's hospital, are made worse by being brought to the hospital " Then there were many instances where, after long attendance as an out-patient at a hospital, the patient consulted a private practitioner and then better results were obtained. The fact was that proper care could not be given at the hospitals because the out-patients came no one knew where from changed from hospital to hospital, disappeared, and there was no means of ascertaining what had caused their diseases or what was the effect of the treatment given The hospital was isolated , it received patients from the outer world but was not in touch with the outer world What effort was made to link hospital treatment with the necessary sanitary changes in the patient's home ? The cause of the disease thus often remained unremoved. The outdoor hospital treatment served as mere patchwork for the continuation of existing evils There was not a "scientific method planned deliberately and definitely for the real cure of the patients " In London, certainly, the Hospital Sunday Fund insisted that an inquiry officer or almoner should be appointed, but little or nothing really effective had been done At most, inquiries had related to some wage standard, but many other facts should be ascertained before it was possible to judge whether a patient was a fit subject for charity If the wage limit was high then many persons would be admitted who could pay , if low, it would be constantly set aside. To show the amount of abuse that existed it would be noted that when the outdoor patients' department was temporarily closed there was a great increase in paying private patients Three hospitals had attempted to make systematic inquiries, but their patients were too scattered and the inquiry should be uniform for all hospitals The first thing necessary was for the medical men themselves to agree who should be admitted To carry out any rule trained almoners were necessary, and such training necessitated one or two years' apprenticeship The almoner should be abl see that the home conditions were in keeping with the requ ments of the treatment and should be well acquainted with Poor-law and with the charities that might help to prov such conditions Where inquiries on these lines had b made Mr Loch found that out of 1920 patients interviewe the course of three months 82 had been referred to provid dispensaries, 104 to friendly societies, 18 to the Poor-law were sent away as being able to pay, and 44 were referre the Charity Organisation Society, and 47 to other agenc thus effecting a reduction of 344 patients. In another the reduction amounted to 397 out of 1443 patients, 27 per cent of the applicants. Such elaborate inquiries w more fair to the poor than a mere arbitrary wage-limit. course, this ran counter to the system of appealing for s scriptions by reason of the number of the cases treat If anything, the number of cures effected, the quality not the quantity, should be the basis of such appeals. to bring about such reforms a central controlling board needed

Dr D E ANDERSON (Paris) then read a paper on Refo in Hospital Management, in which he argued that committees of management had proved a failure and pla the medical staff in a false position The selection of sen officers should be made as in France. Patients should be employed to do menial work in the wards and treated inferior beings They should be allowed to make complai to some impartial authority Many hospitals were in pr tice managed by one single person who was always a layma Those members of the medical staff who failed to curry fav with this individual were soon compelled to resign. T could only be remedied by securing the appointment medical men on the committees of management. T speaker knew of hospitals where medical men were in t majority on the board of management and there no co plaint had arisen In France the directors of hospitals we appointed by the Government and the staff by order of me and after special and lengthy studies and examinatio The pharmacy department was also better managed

Mr E H T NASH (Accrington) read a paper on Hospi Competition and said that the greatest evils arose in lar centres and more particularly in regard to hospitals f special diseases There was much abuse in Lancashi and a wage limit by itself would not suffice to remedy th evil , He related several cases of abuse occurring in his ow practice and complained that at the Manchester Infirma instead of giving a second opinion they kept the patient Therefore, practitioners did not like to send difficult cases the infirmary to obtain a second opinion for fear of losi them altogether

The discussion was now thrown open and Mr J WHITAKER (Great Yarmouth) moved —

> That the Ethical Section desires cordially to thank Mr O S Loc for his attendance and for the valuable information he has imparte on this subject of hospital reform, and the section would ask th Council to take into careful consideration the important suggestio of Mr Loch that a standing joint committee of representative medica men and laymen shall be formed to collect facts already ascertaine investigate proposals for amendment and, in conjunction with th Charity Organisation Society and the British Medical Association tak such further steps as may seem desirable to elucidate the subject an bring about reform

Mr Whitaker explained that he had not included in th motion the names of the readers of the other paper because they were members of the Association and member were naturally bound to work for each other No such obligation rested on Mr Loch and he thought it a goo omen that the debate should have been opened by the abl secretary of the Charity Organisation Society Past effort had failed for want of organisation Such movements a had been attempted were only sectional. The grievance were old and well known to many among them, but they must hammer away and not fear repetition till the end was achieved With the new constitution of the British Medical Association the machinery for action had now been provided.

Dr J DULBERG (Manchester) formally seconded the motion. He confirmed the statement that at the Manchester Infirmary patients were invited to come in and be treated when they were sent by their private medical attendant for a second opinion. Such conduct was opposed to the *esprit de corps* that should prevail throughout the profession.

Mr H. NELSON HARDY (London) protested that a good deal had been attempted in the past, though it was necessary to admit that the results were not encouraging The British Medical Association had appointed a sub committee on medical charities which met in London during the month of June this year and drafted a scheme for the management of out-patient departments of hospitals. It had made 12 recommendations First, notices should be posted to the effect that none but the poor would be admitted. Then an officer should be appointed to question applicants to register their answers, and occasionally to call at their homes to verify these statements. The age, sex occupation, and pecuniary position of each patient should be fully recorded. A wage limit based on local and general conditions should be enforced except in cases of urgency A qualified practitioner should see that no infectious cases were admitted into the waiting rooms. No medical officer should attend more than a fixed number of fresh cases each day and the limit shall be such as to insure a reasonable average space of time being devoted to each patient." When the applicants exceed in number this limit preference should be given to those who were seriously ill and then to those who bring letters of recommendation from doctors or governors" Suitable arrangements should be made for practitioners to consult with members of hospital staffs when they certified that their patients could not pay a consultant's fee. If the medical attendant could not attend personally he should give his patient a sealed statement of the case. Patients should be admitted to the consultation in the order of their arrival. All gratuities to porters, &c., should be strictly prohibited. No charge, however small should be made to out-patients. The out-patient department should coöperate with other institutions for the relief of the poor with medical men, clergy, and others working among the poor Mr Hardy, after enumerating the above recommendations, stated that they had been accepted by six hospitals and were partially applied in other hospitals. They had now facts enough in regard to existing grievances and only needed a definite plan of action.

Dr W MUIR SMITH (Eastbourne) explained that at the Eastbourne hospital the medical officers alone decided whether the applicants should be admitted. Every patient must have a written sanction from his usual private medical attendant.

Dr F E. WYNNE (*Leigh Lancs*) *explained* that in his town there were 40 000 inhabitants mostly colliers, and though many accidents occurred they possessed no hospital When necessary the patients had to be conveyed to the Wigan or Manchester hospitals. Two years ago a movement in view of building a local hospital was started. The local practitioners approved but objected to the creation of an outdoor patients department. He explained how throughout the medical men had been treated with but scant courtesy The outdoor patients' department, they were told was necessary otherwise the workmen and colliers would not subscribe. If the local medical men objected house surgeons could easily be imported and encouraged to set up a practice in the neighbourhood. The public, he thought, had assumed a hostile attitude towards the profession. The recent efforts to organise the profession had engendered a belief that the public were about to lose what they conceived to be their vested right in gratuitous medical service. He was anxious to know what could be done to prevent the establishment of outdoor patients departments.

Mr R. H KINSEY (Bedford) thought that the indoor department was fed from the outdoor department. Though abuses arose out of the ticket system, yet without tickets they could not get subscriptions. But when a governor gave a ticket injudiciously the hospital managers should write to him and expostulate. Good results also had ensued when members of the managing committee occasionally visited the waiting rooms and questioned the applicants. Much of the abuse was due to the medical men themselves. The hospitals competed against each other and tried to show the longest list of applicants.

Dr MAJOR GREENWOOD (London) protested against the acceptance of any sort of payment as it destroyed the charitable aspect of hospitals. Many better-class people went to the hospitals and thought that they had fully met the case by putting silver in the box" He had never found any difficulty in obtaining a second opinion from the staffs of the London hospitals

Dr ALFRED COX (Gateshead) insisted on the growing danger due to the fact that workmen now subscribed such large sums for the maintenance of hospitals that they thought they were paying for the services they received and also expected to govern the hospitals. This would lead to the State or municipal ownership of the hospitals. When so many paid for their maintenance they would inevitably come under public control. The question rested on the trend of economic development, and this went to make the workmen masters of the hospitals. But if the profession could be *organised as the workmen were organised the general* practitioner would also reduce his hours of labour He would then be able to do better work and would get more support than at present from the general public.

Mr J T. J MORRISON (Birmingham) urged that it was necessary to act on economic lines and on the lines of medical science. The first affected their charitable subscribers, for their money was being misapplied. Also, a large number of patients would do better if they paid a private practitioner They would save time lost in waiting and the risk to health due to the unhealthy conditions of the out-patients waiting rooms. He thought that the economic base should be argued more in the interests of the subscribers and of the patients than in the interests of the profession. The science aspects of the question were obvious though lay committees were apt to consider the quantity of patients treated rather than the quality of the treatment In regard to the Hospital Saturday movement he thought that Mr Sampson Gamgee had left the town of Birmingham a terrible legacy He had inaugurated this movement and last year the Birmingham workmen had collected £18 000 Of this sum they had made a free gift of £10,000 to the hospitals and the workmen claimed, and honestly believed that the hospitals and the hospital staff belonged to them. Men earning £2 and £3 a week thought they had a right to be treated in what they considered to be their own hospitals If any protest was made concerning a case of abuse the committee for the sake of peace soon let the matter drop

Mr LOCH was now invited to reply and after expressing his thanks for the reception which had been accorded to his paper he urged that special stress should be laid on the fact that the cure and not the quantity of patients was the main issue. The rule in regard to professional secrecy made it difficult to collect facts that could be put in as evidence. It was as necessary to be scientific in administrative as in professional work and therefore trained experts were needed to apply the principles of reform

The motion as given above was then put and carried unanimously

Mr NASH further moved that—

> When a new out patient department is opened it is essential that, with regard to it, conditions of management should be adopted which recommend themselves to the medical practitioners of the district

This was *seconded by Dr* LOVELL DRAGE (Hatfield) and carried with but a few words of explanation the object being to strengthen the hands of the Leigh Medical Society in its efforts to prevent abuse of the new hospital to be built in that town.

TROPICAL DISEASES.

THURSDAY JULY 31ST

Dr ANDREW DUNCAN (London) opened a discussion on

Dysentery

He said that a discussion of dysentery might be well commenced by considering the unity of the disease. The symptoms of dysentery were pain tenesmus and the passage of blood from the bowel, but these were symptoms common to many forms of intestinal flux Bacteriology had revealed several varieties of micro-organisms Amongst these *might be mentioned Shiga* and Ogata's organism in Japan Flexner's in the Philippines a third variety described as occurring in Egypt, the bacillus coli dysenteriæ of Celli and Fiocca, and pyogenic cocci of various kinds streptococci had been found to excite dysentery in animals bacillus pyolaxeus prevailed in the United States, paramœcium coli had been observed in Cochin China, and there were numerous other micro-organisms found in connexion with forms of dysentery In regard to the question of *amœbic or so-called tropical dysentery in* India Dr Duncan was of opinion that the amœba had nothing to do with the causation of dysentery in that country, and he doubted the scientific accuracy of ascribing dysentery to the amœba in any country There was no relation really between the numbers of amœbæ found and the severity of the dysentery and further the amœba had been found in other ailments and in the normal intestine. Chronic dysentery in India was marked by its infrequency nor were cases with intermissions alternating with exacerbations common Elevation of the temperature was not a marked feature of dysentery nor was the mortality high when the treatment was commenced early in the disease. Large tropical abscesses did not bear any special relation to antecedent dysentery, but apparently multiple abscesses did. Recent Indian reports showed that "in 86 post-mortem cases of liver abscess, in 1900, 40 cases showed evidence of dysentery", and between the years 1896 and 1900 dysentery was absent in 53 per cent. Hepatic abscess was rarely connected with dysentery in the West Indies or with the asylum dysentery in England, and had scarcely been met with during the recent war in South Africa. In the treatment of dysentery there seemed to be no reason to discard ipecacuanha in acute forms, cinnamon appeared to be an excellent substitute when ipecacuanha could not be tolerated. Salines in the hands of many practitioners in India had done great good. *Monsonia ovata* had met with indifferent success Sulphur and Dover's powder in combination were most favourably reported upon by Duprez It would appear, therefore, that dysentery gave different results with regard to treatment by different drugs in different countries

Major W J BUCHANAN, I M S, Deputy Inspector of Prisons, Bengal, contributed a paper on

The Prevention and Treatment of Dysentery in Institutions in the Tropics

Although dysentery, like pneumonia, might be a disease of multiple origin, at present they could clearly point to two forms (1) the amœbic, and (2) the bacillary due to the bacillus of Shiga. The term "amœbic" was often regarded as being synonymous with "tropical," but as the amœbic form of dysentery occurred in places well outside the tropics the name was misleading The amœbic form of dysentery was markedly chronic and had a tendency to relapse, but its main features were that it was intimately associated with liver abscess, with the finding of the amœba, and by the absence of reaction with Shiga's bacillus. Amongst the 1130 cases of dysentery on which Major Buchanan based his observations not a single case of liver abscess was seen in the living or dead Dysentery, although it might be associated with a polluted water supply, would persist when the water-supply had been of excellent quality The disease was also seasonal, especially prevailing during or immediately after the rainy season and reaching its minimum in the dry hot season Good cooking and well cleaned rice, wheat, pulse, &c., had a direct bearing upon the prevalence or subsidence of dysentery The communicability of dysentery would also appear to be an important factor, for by isolation of the sick, disinfection of all bedding and clothing, and disinfection of all stools an epidemic could be arrested. As regarded treatment, (1) rest in bed, (2) milk fresh or curdled and such starchy substances as rice water, sago, arrowroot, &c, and (3) early medicinal treatment were most important. To begin with, castor oil and laudanum were useful, but sulphate of soda was to be recommended *par excellence* One drachm of sulphate of soda in cinnamon or fennel water should be given four, five, or six times daily, until bright yellow soft feculent stools were passed without a trace of blood or mucus Ipecacuanha and enemata might be useful, izal had proved useless, the sulphur treatment was not trustworthy With so simple and efficacious a remedy as the saline method there was no reason for employing any other, for in Major Buchanan's hands, of 1130 cases of dysentery thus treated but nine deaths resulted, and in the last 272 cases not a single death occurred.

Major LEONARD ROGERS, I.M.S, contributed a paper on

Tropical or Amœbic Abscess of the Liver and its Relationship to Amœbic Dysentery

Major Rogers stated that although the thick pus of a liver abscess was often free from amœbæ, yet if a scraping of the abscess wall was examined the amœbæ would be easily found and it was the only constantly found organism in "tropical" or amœbic abscess of the liver Dysentery had been proved by clinical data or by lesions seen in the large bowel post mortem to have been present in 95 83 per cent. of liver abscesses recorded by Major Rogers Patients frequently denied, the fact that they ever had dysentery and yet post mortem the bowel might be found the seat of old or recent dysenteric attacks Although the presence of a liver abscess might appear to coincide with an attack of dysentery it was possible, and in some cases proved, that there had been a previous attack of dysentery which had been forgotten. The amœbic type, as opposed to the catarrhal or bacillary type, of dysentery was associated with the large tropical abscess of the liver In regard to alcohol as a direct factor in causing abscess of the liver there was evidence both for and against, as regards malarial infection, there was no proof that it played a part in the etiology of the disease Major Rogers stated that the commonest seat of single liver abscess was underneath the diaphragm immediately above the liver and involving the liver to but a small extent. He believed that the amœba coli found its way from the gut along the peritoneal cavity to the lymphatics in the under surface of the diaphragm where "being stopped here by the suspensory ligament of the liver it might work its way into the organ at this point." The value of leucocytosis in the diagnosis of liver abscess was discussed by Major Rogers and he considered leucocytosis was most marked in comparatively small deeply seated abscesses of the liver and less in those which were already beginning to come to the surface, in fact, this change was marked in those cases where the diagnosis was most difficult and in which leucocytosis would exclude malarial fever As quinine in a solution of 1 in 5000 would kill the amœbæ, Major Rogers suggested washing out the cavity of the abscess with solutions of quinine They were also worthy of trial as injections into the cavity of a liver abscess after aspiration of the pus as a possible curative measure, especially in such cases as were found to be free from the ordinary pyogenic organisms

Dr PATRICK MANSON, C M G, F R.S (London), wished to pronounce a word of warning against accepting agglutination tests as being a thoroughly trustworthy proof of the efficacy of any particular kind of micro organism in dysentery As a diagnostic test it might be efficient, but as a means of establishing the specific agency it was open to doubt. Dr Manson's treatment for the cases of dysentery that he met with in London, which were necessarily mostly of a chronic type, was (1) rest in bed, however chronic the case, (2) rest to the intestine by non irritating food and easily digested food in small quantities, (3) occasional doses of castor oil, and (4) doses of ipecacuanha lasting over a week and administered daily The amœba seemed to be present in all cases of tropical abscess of the liver, it was not met with in Mott's "asylum dysentery" which was, moreover, amenable neither to ipecacuanha nor to salines. Still, he was not sure that the term "amœbic dysentery" was a scientifically accurate one and warned against accepting a handy name of a disease as being a correct one.

Dr W G ROCKWOOD (Ceylon) believed that dysentery was a communicable disease Ipecacuanha had failed in his hands as a means of treatment, but he had found salines efficacious along with rest in bed and rice water as food Liver abscess was found in a very small proportion of cases of dysentery amongst natives, but it frequently occurred amongst Europeans and he had seen it even in women.

Dr J H MUSSER (Philadelphia) stated that amœbic or tropical dysentery occurred beyond the tropics, as he had seen the disease in Philadelphia, and cases had been reported from Michigan He was firmly convinced of the value of the agglutination test as taught by Flexner, who, in the Philippines, in the West Indies, and in several of the States of America, had corroborated the value of the serum test

Dr EDWARD HENDERSON (late of Shanghai) said that ipecacuanha was largely, and almost solely, used in Shanghai in the "sixties," but that he believed that the majority of cases of catarrhal dysentery tended to get well and that any drug which happened to be given, such as ipecacuanha, often got the credit of bringing about a favourable issue without any justification The old classification of dysentery into "catarrhal" and "diphtheritic" seemed to hold good at the present day, the names only, and no other features of the disease, being changed Some form of bowel complaint always preceded cases of liver abscess in Shanghai.

Mr JAMES CANTLIE (London) said that if treatment by salines benefited dysentery by washing away the deleterious products developed within the intestine the speediest and surest method of purifying the bowel in obstinate cases would be by opening the colon in the right flank and applying flushings directly to the colon, as had been done in gangrenous colitis Major Rogers had described the most frequent site of amœbic abscess of the liver to be between the liver and diaphragm, this was the abscess which he (Mr Cantlie) had named supra hepatic abscess and he had drawn attention frequently to the fact that the pus was sterile and that the amœba coli appeared early on the third day in the pus flowing from the wound Mr Cantlie had failed to find either clinical or post-mortem evidence of dysentery in many cases of liver abscess and he had seen some seven or eight cases of liver abscess which had developed within a few weeks of the patient arriving for the first time in the tropics, when the possibility of dysentery as a cause was totally excluded.

Dr F M SANDWITH (Cairo) said that he regarded asylum dysentery and ulcerative colitis existing in non tropical countries as quite different from the typical dysentery of the tropics. The former disease, however probably also existed in the tropics and readily yielded to treatment. Dr Sandwith had for many years believed that dysentery was an infectious disease and should be treated with the same precautions as typhoid fever As regarded treatment, he had long ago renounced ipecacuanha and he used enemata of at least one litre containing alternately boric acid and sulphate of copper for acute dysentery with benefit.

Inspector-General TURNBULL, R.N stated that he had met with three different types of dysentery in Hong Kong—the gangrenous, the aphthous and the catarrhal. He had operated upon three cases of liver abscess there successfully and although the patients had remained at work in the tropics they had had no recurrence of the disease.

Dr M LOGAN TAYLOR, who accompanied Major Ross's expedition to Sierra Leone read a paper on

Sanitary Work in West Africa

The method of attempting to abolish malaria from Freetown, Sierra Leone was by clearing the premises around houses of anything in which the larvæ of the anopheles could exist. Where the pools were small the water was simply swept out, but larger ones were treated with culicicides—either crude kerosine or crude creasote oil. These were superior to formalin corrosive sublimate, copper sulphate, &c If half a drachm of crude creasote was added to a pint of water in which were adult larvæ and the water was stirred up the larvæ died in five minutes, pupæ were more resistant and would live for an hour or more. Oil applied once a week to a pool of water containing mosquito larvæ effectually prevented any larvæ ever reaching the adult stage.

Dr GEORGE A. WILLIAMSON (Cyprus) sent a communication entitled

Bilharzia Hæmatobia in Cyprus

Hitherto bilharzia had been described in Africa, in Mesopotamia, and in Arabia, but until the past year its presence in Cyprus was not known. Dr Williamson's communication established the fact of its presence there without doubt, as the patient in whose urine he found the ova had never been away from the island of Cyprus.

ERRATUM.—In the report of the discussion on the Differential Diagnosis of Functional and Organic Paralysis published in THE LANCET of August 9th, p. 375, under the remarks attributed to Dr David Drummond it ought to have been stated that in this gentleman's opinion certain signs (Babinski phenomenon, girdle sensation relaxed sphincters, facial paralysis in hemiplegia, loss of knee jerk &c.) were for all practical purposes pathognomonic of organic disease and that he believed that marked ankle clonus was quite consistent with functional disorder

---

THE ANNUAL MUSEUM.

(*Concluded from page 396*)

IV —SURGICAL INSTRUMENTS AND APPLIANCES.

Whilst there was a very excellent assortment of modern surgical instruments presented to view this section was more interesting than usual in regard to therapeutic appliances such as those used for the production of electric rays, ultra violet rays, and heat rays. The accessories of the operating theatre were also well represented. In this section may also be included surgical lints, bandages, splints and the appliances employed in the treatment of deformities. Photo-therapeutic apparatus was well illustrated in the exhibit of the Sanitas Electrical Company of 7A Soho-square, London, W Here the Dermo lamp was shown in action and a number of models of various kinds of light baths were on view Related apparatus in going order was also exhibited by M G Gaiffe of 40 Rue St. Andre-des-Arts, Paris. A static machine with eight ebony plates of 55 centimetres diameter was employed for generating a large amount of current for the production of x rays and high frequency phenomena. Demonstrations were given of the efficiency of the apparatus which included an induction-coil giving a spark of 40 centimetres High frequency apparatus after Professor D Arsonval's design was also exhibited. Opposite to this stall the Electrical Ozone and Light Treatment, of 14 Hanover square, London W, exhibited a model of an actinic bath, an installation of which has recently been completed at Harrogate. The baths are combined with ozone generators and the electrodes employed for the administration of high potential currents are of special form Types of lupus lamps and radiant heat and light baths were shown by the Dowsing Radiant Heat Company Limited of 24, Budge-row Cannon street London E.C. Messrs. Harry W Cox, Limited of 10, 11, and 28 Cursitor street, Chancery lane, London, W C. showed some special x ray and light apparatus. Particular attention is paid to the construction of the coils to avoid a break down in the insulation. A local firm Messrs. Mottershead and Co. of 7 Exchange-street, Manchester showed also an excellent collection of electrical apparatus adapted for medical work, including constant and intermittent current batteries, transformers x ray apparatus high frequency apparatus, and electric motors for massage or for working drills or other purposes. The exhibit of the International Oxy Generator Syndicate Limited, of 21, Southampton row, London, W C proved to be of interest. It consisted of a portable oxygen generator for medical purposes A definite length of iron barrel is provided in which cakes of manganese dioxide and chlorate of potash are placed. A spirit lamp immediately under the tube serves to expel the oxygen which on its way to a collapsible gas holder is first passed through a wash bottle. The entire apparatus does not exceed 20 pounds in weight and its cost is £6, while the cakes for making the gas are from 2*s* to 3*s* 6*d* per dozen. Coming to hospital equipment the exhibit of Messrs John Weiss and Son, of 287 Oxford street London W occupied a very large space and was freely inspected by the visitors. The exhibit included a special operation table anæsthetic apparatus, complete operation cases, and a large number of surgical instruments. Close by Messrs Allen and Hanburys of Plough court, London E.C. exhibited a number of instruments and appliances. These included aseptic instruments, cabinets operation tables a nail cleaner and sterilisers for various purposes. Of similar interest was the exhibit of surgical instruments and appliances of Messrs James Woolley Sons, and Co. of Victoria Bridge, Manchester Messrs Isaac Chorlton and Co. of 17 Blackfriars street, Manchester exhibited a number of ingeniously constructed bedsteads adapted especially for hospital use. The exhibit also included a bed rest, a bed table, and an invalid spring couch. The extraordinary strength of Wood's patent wire mattress is now well known. The Longford Wire Company of Warrington exhibited models of bedsteads fitted with this mattress and also a cycle saddle made with the same wire. The Surgical Supply Association, Limited of 35 Market-street, Manchester is an association composed it is stated of a company of medical men formed on coöperative lines to supply the profession with surgical instruments and the like. The association's exhibit comprised medicine bottles, chloroform bottles, aseptic furniture bandages dissecting instruments bougies and other surgical instruments. We have already commended the petanelle preparations which have as a basis peat fibre possessing antiseptic absorbent and deodorant properties and therefore adapted for surgical dressings. Examples of petanelle clothing accouchement sheets hygienic towelings and other fabrics made with petanelle were exhibited by Messrs. Lait Burke, and Co. of 6, Wool Exchange Basinghall street, London E.C. A number of petanelle disinfectant preparations were also shown The goods of the Sanitary Wood Wool Company Limited, of 26, Thavies Inn, Holborn-circus, London E.C are also disinfectant preparations Wood wool is an efficient absorbent and is the basis of a number of useful preparations—as for example accouchement sheet surgical pads, and the like. The Liverpool Lint Company of Mark-street Mills Netherfield road, North Liverpool exhibited specimens of splint padding surgeons tow absorbent gauze tissue, and a number of special bandages The feature of the exhibit of Messrs. Pocock Brothers of 235, Southwark bridge road London S.E., was the universal invalid tabular water and air bed. The bed consists of several compartments quite independent of each other, an arrangement by which obvious advantages are gained for patient, nurse, and medical man alike Messrs. Mayer and Meltzer of 71, Great Portland street, London, W , exhibited some novel hospital furniture in which great interest was taken This included a patent portable surgical motor for mastoid surgery and a motor for general surgery, an operation table, and an aseptic cabinet, the exhibit including a number of special surgical instruments. Surgical instruments also were shown in great variety by Messrs. Down Brothers of 21, St. Thomas s street, Borough, London, S E , and a model of an aseptic operation theatre with furniture of the most recent type was very generally approved Operation tables, glass hospital ware, surgical instruments, cabinets, and ambulance apparatus were exhibited by the Medical Supply Association of 228 Gray's Inn road, London, W C The "Lawson Tait" spring bedsteads, adapted especially for hospital or invalid use, are well known and a number of appliances thus designated were shown by Messrs George Gale and Sons of Dominion Works, Birmingham. An excellent assortment of lints, dressings, and bandages were shown by Messrs Robinson and Sons, of Wheatbridge Mills, Chesterfield Mills, Chesterfield. Modern surgical instruments were also well represented at the stall of Messrs. W Wood and Son, of 42 and 44, Cross street, Manchester The Domen Belts Company, of 456, Strand, London, W C , exhibited its specialities, including abdominal belts, belt corsets, and suspensory belts Besides a number of scientific instruments, including microscopes specially designed for the use of the medical student, Messrs. Thomas Armstrong and Brother of 88 and 90, Deansgate, Manchester, showed also ophthalmoscopes, retinoscopes, and laryngoscopes. Of the patent appliances for the lame made by the O'Connor Extension Company, of 2, Bloomsbury street, London, W C , we have already expressed a favourable opinion. The exhibit included a new support for flat-foot, the "O'Connor patent extension," which compensates for shortening of the leg and enables ordinary shoes to be worn, and a patent surgical boot with a similar object. Messrs J Gardner and Son, of 32, Forrest-road, Edinburgh, exhibited a large assortment of surgical and medical appliances, many of them the suggestion of the members of the Edinburgh School of Surgery, and a number of instruments and surgical dressings were also exhibited by Messrs. Billings and Sons, of Oxford arcade, Oxford street, Manchester The exhibit of the Holborn Surgical Instrument Company, of 117, Holborn London, E C , was on a quite large scale, its catalogue comprising, it is stated, over 14,000 different instruments. The well known manufacturers of plaisters, Messrs William Mather, Limited, of Dyer street, Hulme, Manchester, exhibited their specialities, including belladonna plaisters of guaranteed alkaloidal strength, surgeons' rubber adhesive plaister, and royal balsamic plaisters identical with those supplied to the army and navy at Scutari Hospital. Lastly should be mentioned the bedsteads designed for special institutions, such as small pox and fever hospitals, made by Messrs John and Joseph Taunton of Belgrave Works, Sherbourne road, Birmingham The patent "diagonal" anti sagging spring bedstead has been supplied in great numbers to the Metropolitan Asylums Board The exhibit included an "epileptic" bedstead, a hospital cot, and a high sided bedstead used for epileptic patients or aged people

V —MINERAL WATERS, BEVERAGES, &C

Both natural and artificial waters were represented although on a somewhat small scale compared with previous years As an example of the former may be mentioned the mineral waters of Harrogate, of Leamington, and of Friedrichshall , these are too well known to need further description. The artificial mineral water exhibits afforded a pleasing contrast to the drugs and surgical appliances A tastefully arranged stall was that of Messrs Jewsbury and Brown, of Ardwick Green, Manchester The exhibit included medicated aerated waters and carbonated lime water and also koumiss. The Chemists' Aerated Mineral Waters Association, Limited of 329, Stockport-road, Manchester, also displayed a variety of aerated waters, including lithia, potash, piperazine, and lysidine. Medical visitors were invited by these exhibitors to inspect the Manchester works The Vichy waters were represented by Messrs Ingram and Royle of 26, Upper Thames street, London, E C , as were also the table water of Ober-selters and Carlsbad waters The Apollinaris Company of 4, Stratford-place, Oxford street, London, W , exhibited specimens of Apenta water drawn from the natural mineral water springs near Buda pest and containing sulphate of magnesia and sulphate of soda. Specimens of Apollinaris water and Johannis water were also shown, while the use and action of a neat rubber stopper for preserving the effervescent properties of these waters in bottle after the cork has been withdrawn was demonstrated

VI —PUBLICATIONS

Several well-known publishers now take advantage of the annual exhibition to bring recent medical publications to the notice of the visitors Amongst these were Messrs W B Saunders and Co of 9, Henrietta street, Covent Garden, London, W C (*medical hand atlases, text-books, &c.*), Messrs. Macmillan and Company of London (manuals of medicine and surgery), Messrs Rebman, Limited, of 129, Shaftesbury avenue, Cambridge circus, London, W C (medical, surgical, and hygienic publications), Messrs. J B Lippincott and Co , 5, Henrietta street, Covent Garden, London, W C (medical dictionary, manuals, &c.), Messrs. William Green and Sons, Edinburgh (Encyclopædia Medica and *other medical works*), Messrs John Wright and Co , Bristol (the Medical Annual and the Golden Rule Series in medicine and surgery), Messrs Baillière, Tindall, and Cox, 8, Henrietta street, Covent Garden, London, W C (Medical Monograph Series, Gould's Dictionary, and atlases of anatomy and physiology)

VII —MISCELLANEOUS

In this section we may give a brief account of the motor cars and other vehicles exhibited which claim some attention, since they were offered as meeting the special needs of the medical practitioner Messrs. F Wilkinson and Co of 25A, Cornbrook-road, Manchester, exhibited a model of the "steamobile" with an eight horse-power engine. The oil burner is atmospheric and may be started with a match. By an automatic contrivance the fire is completely cut off when the steam pressure is up By means of a bypass the burner is automatically lit again. The Benz Motor Car Company, of 251, Tottenham Court-road, London, W C , showed the "Doctor's Ideal Car" and the Stirling Motor Carriages Company, Limited, of Granton-Harbour, Edinburgh, showed examples of the "Stirling auto-car" specially designed for the use of medical men, and the Gardiner Serpollet steam carriages (94, Victoria street, Westminster, London, S W) were available for trial runs up and down Oxford street. Amongst coach builders showing special designs of carriages for the use of medical men were Anne Cowburn of Cheetham hill-road, Manchester , Mr John Roberts, of Stretford road Carriage Works, Manchester , Messrs Slack Bros , of 44, Oxford-street, Manchester , and Messrs. Joseph Cockshoot and Co of Newbridge street, Manchester Messrs Worsnop and Co of the Carlton Lamp Works, Halifax, exhibited a number of lamps for carriages and motor cars, including acetylene and petroleum lamps. Mr Richard Sibbitt of Riley street, Coventry, showed the "doctor's bicycle," built especially for medical men Again, the patent brougham ambulance of Messrs. Wilson and Stockall of Bury, Lancashire, is well worth attention A recumbent patient is placed in position in the brougham through a door at the back. There are doors also at the sides with opaque windows which prevent the patient from being seen from the street though he can see into the street himself The brougham is fitted with a stretcher and special rubber air-bed, an arrangement which is collapsible so that when the stretcher and frame are removed the brougham can be used in the ordinary way It is convenient to mention in this section also the non inflammable flannelette exhibited by Messrs Whipp Bros and Tod, Limited, of Manchester Demonstrations were given showing the comparative non inflammability of the fabric, whilst its softness is unimpaired. The result is obtained, we believe, by treatment with certain chemical salts We have long recognised the necessity of rendering flannelette much less easily inflammable than it is and a word of commendation is due to these manufacturers for accomplishing that end with a distinct degree of success Finally the exhibit of the Shannon, Limited, of 49, Moseley street, Manchester, should be mentioned as demonstrating a system of letter-filing, &c. calculated to be of service to the busy medical practitioner

Public Health and Poor Law

LOCAL GOVERNMENT BOARD

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD

Report on Recent Sanitary Administration in the Borough of Falmouth, by Dr G S BUCHANAN[1]—In THE LANCET of April 14th 1900 p. 1090 we commented on reports which had been presented to the Local Government Board by Dr Buchanan in connexion with an outbreak of enteric fever in Falmouth during 1899 In October 1901 he made a re-inspection of the locality and now states that the town council has shown much greater activity than it did formerly in sanitary matters. The report nevertheless clearly shows that at the time at which his last inspection was made there were present all the conditions suitable for the spread of enteric fever It would not be necessary even if it were possible, to recapitulate all the details mentioned by Dr Buchanan, and it must suffice to point out that the conditions of the drainage and of the water supply are about as unsatisfactory as it would be possible for them to be. The sewers are leaky they were not properly laid in the first place and the deficiencies have not since been generally made good Dr Buchanan says In two streets defective portions of the sewers have been renewed. Often in making new connexions of a house drain with the sewer the joint or joints of the latter which were exposed were noticed to be leaky and have been patched up. Otherwise the sewers throughout the borough which I described as generally showing leakage on account of the clay working out of the sockets of the pipes remain in the same condition as before. There can be no reasonable doubt, therefore, that the soil is saturated with sewage The borough is intermittently supplied with water by a company the water is delivered from sources open to pollution and is not efficiently filtered, the service pipes in many cases were laid in the most irregular manner with only bit joints, there were no properly made plumber s joints. This description of the service pipes was given by Mr C E Phillips M. Inst. C.E. in a report he made at the instance of the town council of Falmouth. The result of this engineer s investigation confirmed the probability of a suggestion which Dr Buchanan had previously made that the water was liable to pollution from insuction of fluid from the soil when the water is turned off and the mains are emptied It is the custom to shut off the supplies on Fridays, and the pipes are often emptied by rapidly running off the water into the harbour thereby increasing the opportunities of insuction. The town council has manifested its activity by adopting a scheme for laying an iron intercepting sewer to an outfall beyond the outer harbour but it does not propose to deal with the defective sewers which permeate the town. The new scheme has been submitted to the Local Government Board and it is found that amendments are desirable in certain important matters of detail. The intercepting sewer is undoubtedly wanted but it is perfectly clear that it alone will not make Falmouth into a sanitary town. In order to accomplish this it is necessary that all defective sewers should be made good, that the domestic fittings should be efficient, that the purity of the water supply should be ensured and that the service pipes should be sound In regard to the sewers it appears from Dr Buchanan report that most of them will have to be relaid. It is evident that the town will have to provide for the expenditure of a considerable amount of money but fortunately at present the rates do not exceed 3*s.* in the £. From the point of view of economy alone the borough authorities would be well advised to have the necessary work done well and done at once. Falmouth is naturally a place of great beauty In its present unhygienic state it will be avoided by all sensible people who are not obliged to live there.

REPORTS OF MEDICAL OFFICERS OF HEALTH

The City of London.—The night population of the City has been steadily diminishing since 1861 and at the last census it amounted only to 27 639 The birth rate was 13 7 per 1000 for the whole registration district of the City and 8 9 per 1000 in the Allhallows and 18 1 in the St. Botolph sub-registration districts. Dr W Collingridge devotes much attention in his report to the subject of tuberculosis which, in consequence of the large meat markets within the City boundary is a matter of serious moment for the corporation, more particularly so when the report for 1901 of the veterinary inspector of the City shows that of 500 cows examined after slaughter 48 8 per cent. were tuberculous. In July 1901, the corporation adopted the voluntary notification of phthisis and agreed to pay the usual fee in respect of each case notified. The corporation has followed the example set by Kensington and other boroughs and has appointed a female sanitary inspector whose duties have now been defined by regulation, approved by the Local Government Board. In connexion with the question of workshops Dr Collingridge has drawn up a diagram to show the number of bakehouses in the City which are above or below ground. Of the total (41) seven are above ground and 34 below During the hot weather of last year a special inspection was made of the sanitary conveniences at the 21 railway-stations within the City boundaries. In all these, save Bishopsgate, Broad street, and Liverpool street serious sanitary defects were discovered and remedied. We should be glad to see an inspection of this nature extended to every station in the United Kingdom. It is within our own knowledge that a large proportion of these places are in quite a disgraceful condition. With respect to the better control of ice-creams the corporation decided to support the Bill promoted by the London County Council provided that within the City the corporation should be the sole authority for carrying out the provisions of the Act This is we imagine, not quite in keeping with the scheme which the County Council have in view The attitude of the corporation towards the County Council s milk clauses is very similar—i e. they approve the clauses provided the City has concurrent powers with the County Council in the administration of such clauses. With regard to the condemnation of unsound food it is stated that during 1898-1900 no fewer than 31 327 tins of condensed milk 13 180 tins of fruit and 22,554 miscellaneous tins were destroyed and that during 1891 265 cartloads of unsound food were similarly dealt with a trade refuse. No less than 415,510 tons of meat were delivered at the corporation markets during 1901 and of this amount 0 306 per cent. was condemned. An instructive chart relating to the supply and seizure of meat from 1877 to the present time is contained in the report before us, and there is a second chart showing the origin of meat delivered at the central markets Smithfield from 1898 to 1901 A somewhat remarkable seizure of the carcasses of 30 tuberculous pigs took place during the year All these pigs had tuberculosis of the thyroid glands and some other glands were similarly involved These pigs were part of a consignment of 74 which were purchased in the Ipswich market, and the detection of the malady reflects great credit upon Mr Downs the inspector who effected the seizure. We are quite in accord with Dr Collingridge when he suggests that certain of the funds available for technical education might be usefully applied towards the spread of knowledge as to the characteristics of sound and unsound food We fear that a large number of officers who act as meat inspectors are not sufficiently educated on this subject to allow of their doing justice either to the public or to the butchers

St Marylebone Borough.—Mr A. Wynter Blyth has opposed to those provisions of the County Council (General Powers) Bill which enable the officers of the London County Council to *inspect dairies either* within or without the county of London in cases where the milk is supposed to have caused the disease. Mr Blyth is evidently in favour of the power in question being granted to the borough council and he expresses regret that the London Council constantly in their policy depart from this great and essential principle of referring all detail to local authorities and evince a desire to initiate and carry out themselves the most minute detail with regard to sanitary inspection " It appears to us, however that in an aggregation of people such as constitutes the metropolis where the several sanitary areas are immediately contiguous [illegible] are desirable

Newport Borough [illegible] furnishes in his current annual [illegible] the death rate from phthisis [illegible] Such rate rose until 1871 when the downward curve commenced which has continued almost uninterruptedly up to the present. Phthisis is not yet notifiable in Newport, but the disinfection of rooms takes place after death from this disease The borough of Newport has for several years taken an active share in the control of chemical preservatives in milk, &c , and it has now set a good example by adopting as a working basis the recommendations of the recent departmental committee on food preservatives

---

[1] London: Eyre and Spottiswoode. 1902. No. 178.

Cornwall County Council —This county council has not maintained the reputation for sanitary reform which it possessed in the days when Mr Sylvanus Trevail was chairman of the sanitary committee There is a notable falling off in the character of the reports and the one now before us affords but very little useful information , indeed, the report is practically devoted to the statistics of the county From these we learn that phthisis is increasing instead of, as in the country generally, decreasing It is we think, to be regretted that the county council does not appoint a properly qualified medical officer of health who would use the valuable material at his disposal for a useful end.

St Helens Urban District —The infant milk dêpot in this town still carries on its useful work, but Dr F Drew Harris is disappointed at the apathy of the public in the matter The results, as far as they go, appear to be highly encouraging, as is indicated by the table given below —

Year	Number of children on books	Death rate per 1000 among children at depôt	Infantile death rate.
1899	232	103	157
1900	332	102	188
1901	282	106	175

i e , there is apparently a saving of life of 70 per 1000 among children using the milk. The income from the sale of milk during 1901–1902 was £245 16*s* 3*d* , and the expenditure £402 16*s* 3*d* There was therefore, a deficit to be paid for out of the rates of £157 But, as Dr Harris observes, the cost to the town is small in comparison to the benefits which accrue

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 6785 births and 3883 deaths were registered during the week ending August 9th The annual rate of mortality in these towns, which had been 13 9 and 14 1 per 1000 in the two preceding weeks, declined again last week to 13 6 per 1000 In London the death rate was 13 4 per 1000, while it averaged 13 7 in the 75 other large towns. The lowest death rates in these towns were 0 9 in Smethwick, 3 0 in Willesden, 5 5 in East Ham, 6 5 in Rotherham, 6 9 in Hornsey, 7 4 in Burnley, 7 6 in Bournemouth, and 7 7 in Swansea , the highest rates were 18 7 in Huddersfield, 18 9 in Gateshead, 19 0 in West Bromwich and in Tynemouth 20 2 in Liverpool and in South Shields, 20 9 in Hanley, and 23 7 in Wigan The 3883 deaths in these towns last week included 584 which were referred to the principal infectious diseases against 476, 522 and 533 in the three preceding weeks , of these 584 deaths 186 resulted from diarrhœa, 113 from whooping cough, 107 from measles, 81 from scarlet fever 49 from 'fever" (principally enteric), 42 from diphtheria, and six from small pox. No death from any of these diseases was registered last week in Willesden, East Ham, Hastings, Bournemouth, Great Yarmouth Smethwick, Warrington, Rotherham or Swansea , in the other towns they caused the highest death rates in Portmouth, Bristol, Hanley Walsall, West Bromwich, Liverpool, Bootle, Wigan, and Middlesbrough The greatest proportional mortality from measles occurred in Bristol, Stockton-on Tees, Gateshead, Cardiff, and Rhondda , from scarlet fever in Burton on Trent, West Bromwich, Birmingham Wigan and Middlesborough, from diphtheria in Tottenham , from whooping cough in Portsmouth Norwich, Hanley, Barrow in Furness, Huddersfield, Tynemouth and Cardiff , from "fever" in Ipswich , and from diarrhœa in Leyton, Walsall Stockport, Birkenhead, Liverpool, and Bootle Of the fatal cases of small pox registered last week four belonged to London, one to Leicester, and one to Liverpool, but not one to any other of the 76 large towns There were 239 cases of small-pox under treatment in the Metropolitan Asylums hospitals on Saturday, August 9th, against numbers declining from 1515 to 305 on the 15 preceding Saturdays , 21 new cases were admitted during the week, against 48, 23, and 44 in the three preceding weeks. The number of scarlet fever patients in these hospitals and in the London Fever Hospital at the end of the week was 2591, against 2377, 2486, and 2562 at the end of the three preceding weeks , 296 new cases were admitted during the week, against 333, 397, and 382 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 155, 128, and 135 in the three preceding weeks, declined again last week to 131, and were 28 below the corrected average number The causes of 63, or 1 6 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in West Ham, Bristol, Leicester, Nottingham, and in 48 other smaller towns , the largest proportions of uncertified deaths were registered in Coventry, Liverpool, Wigan, and Blackburn

HEALTH OF SCOTCH TOWNS

The annual rate of mortality in the eight Scotch towns, which had been 14 7, 15 8, and 16 6 per 1000 in the three preceding weeks, declined again to 12 9 per 1000 during the week ending August 9th, and exceeded by 0 3 per 1000 the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 12 2 in Paisley and 12 6 in Leith to 15 6 in Perth and 18 9 in Greenock The 449 deaths in these towns included 16 which were referred to whooping-cough, 16 to diarrhœa, five to measles, four to "fever," three to scarlet fever, and two to diphtheria. In all, 46 deaths resulted from these principal infectious diseases last week, against 55 and 48 in the two preceding weeks. These 46 deaths were equal to an annual rate of 1 4 per 1000 which was 0 6 per 1000 below the mean rate last week from the same diseases in the 76 large English towns The fatal cases of whooping cough, which had been 15, 13, and seven in the three preceding weeks, rose again to 16 last week, and included nine in Glasgow, two in Edinburgh, two in Paisley, and two in Leith The deaths from diarrhœa, which had been 21 and 19 in the two preceding weeks, further declined last week to 16, of which nine occurred in Glasgow, two in Edinburgh, two in Dundee, and two in Aberdeen The fatal cases of measles, which had been 10 and 12 in the two preceding weeks, declined again to five last week, and included three in Edinburgh. The three deaths from scarlet fever, two of which were registered in Glasgow, corresponded with the number in the preceding week. The fatal cases of "fever," which had been one and three in the two preceding weeks, further rose last week to four , while the deaths from diphtheria declined to two last week, having numbered four in each of the two preceding weeks The deaths referred to diseases of the respiratory organs in these towns, which had been 80 and 70 in the two preceding weeks, further decreased last week to 63, but exceeded by 19 the number in the corresponding period of last year The causes of 12, or nearly 3 per cent., of the deaths registered in these eight towns last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 20 2, 20 2, and 21 2 per 1000 in the three preceding weeks, declined again to 20 2 per 1000 during the week ending August 9th. During the past four weeks the death rate has averaged 20 5 per 1000, the rates during the same period being 13 8 in London and 15 5 in Edinburgh The 147 deaths of persons belonging to Dublin registered during the week under notice showed a decline of seven from the number in the preceding week, and included 30 which were referred to the principal infectious diseases, against 14, 15, and 29 in the three preceding weeks , of these 20 resulted from measles four from "fever," three from diarrhœa, and one each from scarlet fever, diphtheria, and whooping-cough These 30 deaths were equal to an annual rate of 4 1 per 1000, the death-rates last week from the same causes being 2 4 in London and 1 4 in Edinburgh The fatal cases of measles, which had risen from three to 18 in the six preceding weeks, further increased last week to 20. The deaths from "fever" which had been one and two in the two preceding weeks, further rose to four last week. The fatal cases of diarrhoea, which had been three and five in the two preceding weeks, declined again last week to three. The 147 deaths in Dublin last week included 31 of children under one year of age and 31 of persons aged upwards of 60 years; the deaths of infants slightly exceeded the number in the preceding week, while those of elderly persons showed a decline. Three inquest cases and two deaths from violence were registered during the week; and 57, or more than a third of the deaths, occurred in public institutions. The causes of 10, or nearly 7 per cent. of the deaths registered in Dublin last week, were not certified.

THE SERVICES

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel H. Charlesworth, C.M.G., is appointed to succeed Lieutenant-Colonel W. G. Don, A.M.S. (retired), at the depôt of the London Recruiting District, and Lieutenant-Colonel J. Latchford (retired) is appointed medical officer in the Dublin Recruiting District. Lieutenant-Colonel H. E. R. James is ordered to London for temporary duty in connexion with the Army Medical School and Medical Staff College. Lieutenant-Colonel O. W. S. Magrath is appointed to the North Eastern District for duty.

Lieutenant-Colonel William S. Pratt to be Colonel. Captain G. O. Phipps is placed on temporary half pay on account of ill health. Dated July 6th, 1902.

VOLUNTEER CORPS.

Royal Garrison Artillery (Volunteers): 1st Fifeshire: The undermentioned Surgeon Captains to be Surgeon Majors:—J. W. Moir and R. B. Graham. Supernumerary Surgeon Captain S. Linton to be Surgeon Major and to remain Supernumerary. 1st Kent: Surgeon Captain R. J. Bryden to be Surgeon Major. 2nd Kent: Surgeon Captain J. F. Tabb to be Surgeon Major.

Royal Engineers (Volunteers): East London (Tower Hamlets): Surgeon Captain W. A. Dingle to be Surgeon Major.

Rifle: 2nd Volunteer Battalion the Prince Albert's (Somersetshire Light Infantry): Surgeon Captain C. J. Marsh to be Surgeon Major. 2nd (Berwickshire) Volunteer Battalion the King's Own Scottish Borderers: John Paxton to be Surgeon Lieutenant. 2nd Volunteer Battalion the South Staffordshire Regiment: Surgeon-Captain J. S. Wilson to be Surgeon Major. 2nd Volunteer Battalion the Welsh Regiment: Surgeon Captain J. A. Jones to be Surgeon Major. 3rd Volunteer Battalion the Welsh Regiment: The undermentioned Surgeon-Captains to be Surgeon Majors:—C. Downing and J. T. Thompson. 1st Wiltshire: Surgeon Captain H. P. Tayler to be Surgeon Major. 2nd Volunteer Battalion the Wiltshire Regiment: Surgeon Captain H. J. Mackay to be Surgeon Major. 5th (Deeside Highland) Volunteer Battalion the Gordon Highlanders: Alexander Cruickshank to be Surgeon-Lieutenant.

VOLUNTEER INFANTRY BRIGADES.

1st Lothian: Surgeon Major A. D. Webster, the Queen's Rifle Volunteer Brigade the Royal Scots (Lothian Regiment), to be Brigade-Surgeon Lieutenant-Colonel whilst holding the appointment of Senior Medical Officer to the Brigade.

MENTIONED IN DISPATCHES.

A General Order dated July 4th, 1902, publishing a report from Major General C. C. Egerton, C.B., D.S.O., on the operations undertaken against the Mahsud Waziris has been received from the Government of India, in which the following passages occur:—Colonel G. McBride Davis, M.D., C.B., D.S.O., Indian Medical Service, Principal Medical Officer, is an officer of very great practical experience and administrative ability, to whose power of organisation it is largely due that the medical arrangements have been able to cope with the situation. Lieutenant-Colonel W. A. Mawson, Indian Medical Service, Principal Medical Officer Derajat District, had charge of the medical arrangements during the passive blockade and was largely responsible for those during the active operations. Before the arrival of the field hospitals he had with scanty means to provide for the medical needs of a number of regiments which arrived with hospitals on the relief scale, and this he did in an efficient manner. He has displayed administrative ability and rendered valuable service.

The following names of officers of the Indian Medical Service are also mentioned:—Captain W. H. Cox, Major M. A. Ker, Lieutenant H. D. Pello, and Lieutenant A. B. Fry.

THE LATE WAR IN SOUTH AFRICA.

We must, of course, be content to await the publication of the complete official history before we can arrive at correct knowledge of all the facts and circumstances connected with the war and learn the sacrifices which it has entailed. We know fairly well the sum total of the deaths, but not the number of these and of the wounded as distributed over the several engagements and as appropriated to each of them respectively. According to the War Office returns issued from the beginning of the campaign in South Africa on Oct. 11th, 1899, to the end of May, 1902, the total death casualties amounted to 22,450, of which 1080 were officers and 21,370 were rank and file. Of the above the deaths from sickness were 339 officers and 12,911 non-commissioned officers and men. The wounded (excluding those who died from wounds) numbered 1668 officers and 19,143 rank and file. These numbers only cover the war period, and to them must be added the returns of sickness and death which have since appeared in the public prints up to the present time. As regards our late enemy, the Boers, we only know approximately the total strength of the forces which they brought into the field against us—namely, from 50,000 to 100,000, according to different estimates. We have no accurate knowledge of the amount of their losses in killed and wounded and by sickness.

THE TRANSPORT SCANDALS.

The alleged overcrowding scandals on board the transports *Drayton Grange* and *Britannic* are to be much lamented. They occur most inopportunely at a time when our colonies have been doing their best to aid the mother country and helping to make the Empire something more than a geographical expression. A thorough investigation will, it is understood, be undertaken at once by a joint Imperial and Colonial commission, and we consider it premature to impute any blame or indeed to express any opinion beyond one of regret until the facts are known.

IMPERIAL YEOMANRY HOSPITAL FUND.

On August 11th at Devonshire House Queen Alexandra distributed medals to the staff of the Imperial Yeomanry Hospitals from South Africa.

Captain H. E. Haymes, R.A.M.C., has received the King's permission to accept and wear the decoration of the Medjidieh of the Fourth Class conferred upon him by His Highness the Khedive of Egypt, authorised by His Imperial Majesty the Sultan of Turkey, in recognition of services rendered by him to His Highness while employed in the Egyptian Army.

"Audi alteram partem."

ON THE USE OF THE TERM "BLASTOMA."

To the Editors of THE LANCET.

SIRS,—That I find myself in the heart of the Rocky Mountains rather than, as I had hoped, in England, will explain the long delay in answering the letter by Dr. C. J. White which appeared in your issue of June 14th, p. 1723, and that of Dr. Herbert Snow which appeared in the *British Medical Journal*. An answer would seem necessary, for neither correspondent takes note of my main contention or appears to realise its importance. The question as to whether, other things being equal, the term "blastoma" would fittingly describe a particular group of tumours is purely academic and neither here nor there once it is shown that the term has already been employed with a different meaning. Unless we regard the law of priority chaos results. When continental writers and readers already understand the order of conditions to be signified by this term, imagine the confusion if English writers, following either Dr H Snow or Dr White, use it in another and very much restricted sense This is why I felt it imperative to point out that Dr White must choose another name

It is no valid argument to urge that Klebs's use of the term is to be forfeited because he included under the term conditions which we in general, or anyone in particular, no longer places among the true tumours—any more than it would be to propound that we must no longer employ the term "fish" to indicate the division Pisces, because in times past this comprehended whales, cuttle fish and may be, lobsters, which now we place elsewhere.

Failing a permanent committee—of the International Medical Congress, for example—which should decide matters of nomenclature, if our terminology is not to become a very Babel, we have to adhere as nearly as possible to the laws of nomenclature accepted by other branches of biological science. According to those laws, so far as I understand them, it is legitimate to introduce new designations for large classes and divisions of objects, but for what correspond to genera and species no names must be introduced which have already been employed in another sense even if in not so fitting a manner Thus "blastoma' is excluded from being utilised as a generic name I must disagree with Dr White, however, as to the inappropriateness of "blastoma" as a designation for true tumours For if, as he acknowledges, a leading characteristic of these true tumours is their capacity for independent growth within the organism—independent, that is, of the needs of the organism—it would be difficult to select a word which better expresses the idea of autonomous germination. Following Dr White's line of argument it is open to anyone to speak of those chondromata, gliomata, &c , which originate from embryonic cell rests—from "indifferent cells"—as blastomata, leaving it for the future to determine which meaning of the term gains acceptance—his or Dr White's or Dr Snow's or Klebs's !

One last word with reference to the deviation pointed out by Dr White in my nomenclature from that of Professor Klebs As he notes, Klebs divided the blastomata, or true tumours, into the blastomata proper and the terato blastomata or teratomata—another instance of loose nomenclature leading to confusion, for, using the same word to designate both order and class, one is never certain which is indicated save when a qualifying adjective is used. In such circumstances it is wholly lawful to select either usage of one s original authority, and, as Klebs gave the alternative names of terato blastoma and teratoma for the one class, I selected blastoma for the other I admit that I could with equal propriety have elected to employ blastoma as the name for the order and might have entitled the classes eublastoma and terato blastoma respectively This might indeed, have been better, but I believe that I acted with correctness I agree with Dr White in this, that, with him, I would remove many conditions which he includes under the "progressive hypertrophies" from the category of true tumours

I am, Sirs, yours faithfully,

Field British Columbia July 11th 1902. J GEORGE ADAMI

MOTOR BICYCLES

To the Editors of THE LANCET

SIRS,—I have ridden about 2000 miles on an "Excelsior" motor bicycle since May this year and I can strongly recommend these machines to medical officers of health of rural districts and other practitioners who have long distances to cover I have ridden my machine in all weathers and over all sorts of roads—mostly hilly As an example only a fortnight ago I started from my house, which is 240 feet above sea level and ran some 70 miles through the Peak, crossing the 1250 contour line more than once On another occasion I took a friend in a trailer over 70 miles To show how easy the machine is to manipulate I lent it one day to a medical neighbour This was at three o clock in the afternoon In five minutes he had mastered it and at six o clock he returned it, having done a round of 28 miles To appreciate the full significance of this performance I ought to add that my neighbour is a fine specimen of a man.

I find my accumulator wants recharging about every 700 miles This costs me 9*d* My petrol bill works out at about one tenth of a penny per mile The machine I have is one and a half horse power I have seven inch cranks and have the machine geared for pedalling to 60 inches The result is that if I ran short of petrol or my accumulator ran down I can remove my belt and pedal along comfortably at six miles an hour To those of your readers who are contemplating purchasing a motor bicycle let me recommend them to peruse a few numbers of that excellent paper *Motor Cycling* As a stimulant and a remedy for insomnia I can thoroughly recommend motor cycling for any except the most weakly , the rider must, however, be warmly clad. If any of your readers desire further information I shall be glad to give it if I can

I am, Sirs, yours faithfully,

PERITYPHLITIS

To the Editors of THE LANCET

SIRS,—In July, 1530, Erasmus wrote to Melanchthon[1] "I have been ill these three months—suffering, sick, and miserable Medicine made me worse First I had a violent pain , then came a hard swelling down my right side to the groin, gathering at last at the pit of my stomach, as if a snake had had my navel in his teeth and was coiled round the umbilicus Shooting pangs continued so that I could neither eat nor sleep The surgeon nearly blistered me to death , at length the tumour was cut open, sleep returned, and I was relieved. Now I crawl about feebly, but am not out of the doctor's hands " Erasmus thought himself the subject of stone in the bladder , but was this not perityphlitis ? and is not this an example of an operation ? He lived for six years afterwards and seemed to have had rather better health

REAPPEARANCE OF RASH AND ALL SYMPTOMS IN A CASE OF SCARLET FEVER

To the Editors of THE LANCET

SIRS,—A note in this week's issue of one of the medical papers has suggested to me that the publication of the following case may be interesting On June 6th, 1899, two brothers were attacked with scarlet fever in a house where there were already four other cases In the one to whose case these notes refer the symptoms were all well marked and in some respects severe—high temperature, loss of appetite, nausea, sore throat, enlarged glands, profuse rash, and drowsiness amounting almost to stupor His progress was of the usual kind , desquamation began about the same date as in the other five cases On June 20th all the initial symptoms, even the marked stupor, were reproduced, accompanied by a temperature of 102° F On June 21st the rash reappeared. Perhaps the most remarkable point in the recurrence was that on June 28th erythema nodosum was well marked on both legs and had probably been present in a slighter form for a few days This subsided quickly but reappeared on July 10th and increased in severity up till July 13th. The first attack of erythema was 22 days after the appearance of the first rash, or probably its commencement may be dated as a little earlier The second attack commenced 19 days and was most severe 22 days after the appearance of the second rash. Desquamation was complete on July 29th. Both brothers were discharged together and no infection was subsequently conveyed to others

THE DUTIES OF A MEDICAL MAN AND THE LAW OF LIBEL

To the Editors of THE LANCET

SIRS,—The questions involved in the case of a married woman contracting syphilis recently referred to in your columns are of such importance that I trust I may be excused if I submit the following

1. In the interest of the wife, the late Mr Henry Lee drew attention to the fact that in a man who had acquired syphilis previous to marriage a urethral discharge or irritation about the penis, accompanied by an increased mucous discharge

---

[1] Froude s Life and Letters of Erasmus p 392.

from the urethra, might appear and so infect the wife with syphilis. The husband (granted that there was no freshly acquired disease on him) believing himself cured of syphilis and that his wife could not have become infected without having exposed herself to the contact of primary disease, would have no alternative but to consider that the wife had been unfaithful The most cruel injustice has in this way through an erroneous pathology been inflicted." In the interest however of the husband he goes on to state that it sometimes, although more rarely happens that the husband is the party who suffers from these mistakes. I have been engaged in more than one trial where the wife or her friends have sought to obtain a divorce on the ground of the husband having contracted disease after his marriage and communicated it to his wife , the whole class of cases to which I am now referring show that secondary affections of the existence of which the husband may have been unconscious at the time of his marriage may recur and be the means of imparting constitutional syphilitic disease This may happen before impregnation although it is much more common afterwards.[1] Pregnancy moreover in many cases determines syphilitic manifestations in a woman and in successive pregnancies recurring manifestations may simulate a first attack.

2. The law of libel in syphilis is remarkably strong In all other cases of libel injury or loss to the person libelled has to be shown but the mere fact of stating that a person has syphilis has been declared to be a libel. To quote from Dr Blake Odgers's text-book on libel it has been decided that he has the pox (*simpliciter*) shall be taken to mean he has the small pox, but if any other words be used referring to the effect of the disease or the way in which it was caught or even the medicine taken to cure it, these may be referred to as determining which pox is meant. So that the position is that though one can mention casually the fact of anyone suffering from most diseases if one says that he or she has syphilis an action for libel might be the result whether the statement is true or otherwise.

The legal opinion therefore, of those who have studied the problem, and to whom I am indebted for their kind expression of views is that publication of a wife's disease to the husband would undoubtedly be sufficient to cause an action to lie against the medical attendant at the suit of the wife. If the communication was verbal the action would be for slander if in writing the action would be for libel. In either case the truth of what the medical men had stated—if proved by him—would be a complete defence and even if there was an error in diagnosis it would probably be held to be privileged unless the plaintiff could rebut privilege," but it would not lessen the risk to the medical attendant of an action being brought and of expense. On the one hand, therefore, an action would lie which if brought would, even if the medical man was acquitted of slander or libel probably injure his professional prospects. On the other hand, probably no woman would face finding herself in the witness-box when a chief party in such a case. We have, however further the duty of the medical man in the first place to prevent the spread of the disease" balanced by the possible accusations between husband and wife and the possibility of an action for divorce or separation in which the medical man would have to give evidence, perhaps to the injury of his professional reputation. The question naturally arises whether it would be possible so to alter the law of libel that while medical men should still be liable if they improperly divulge information obtained in the course of their practice they should yet be in a position at once to instruct any patient or wife or husband or both as to the nature of the disease with a view to prevent transmission and ensure treatment without consideration of possible consequences.

I am Sirs yours faithfully
J. A. SHAW MACKENZIE.

MANCHESTER

(FROM OUR OWN CORRESPONDENT)

The Infirmary Site

AT the meeting of the Manchester city council on August 6th another step was taken as to the infirmary site. Two of the streets surrounding it are narrow and already the business traffic connected with the warehouses is more than can easily be accommodated, while the tram lines which are to be taken through them to relieve the congestion of Piccadilly will add greatly to the inconvenience already existing for the passenger traffic is growing rapidly These streets will serve as a by pass and a backwater for the trams but they will have to be widened considerably The plans for rebuilding the infirmary were made apparently without regarding the evident necessity for widening George-street and Parker street, which can only be done by taking what is wanted from the infirmary area. The resolution carried at the council meeting was that the improvement and building committee be requested to lay down such building lines as they think will be adequate for the future traffic of these thoroughfares. The reduction of the infirmary area thus foreshadowed would have increased the difficulty of carrying out the rebuilding scheme The chairman of the improvement committee said it was the duty of the corporation to take very seriously into consideration what should be done with the site in Piccadilly now that the trustees had so clearly decided in favour of the Stanley-grove site. The value of the infirmary site has been variously estimated up to £400 000 The best use it could be put to would no doubt be to have it laid out as an open space, with grass shrubs and flowers in the fervent hope that with the diminution of the pall of smoke now brooding over us (supposed to be in prospect) they would grow and impart a little cheerfulness to our begrimed and dismal city The next best would be to clear away all the present buildings and occupy a portion of the area with an art gallery and free library the rest of the ground being left open and suitably planted. In this case a receiving hospital would have to be provided in a sufficiently central position It remains to be seen whether the city will act up to the value of the opportunity

The Housing Question at Eccles

The town council of Eccles is beginning to deal with the housing question At the meeting on August 6th the minutes of the insanitary area sub-committee, which had passed a resolution inviting plans for laying out the land comprised in the scheme sanctioned by the Eccles (housing of the working-classes) order 1902. were adopted Provision is to be made for the accommodation of at least 170 persons who may be displaced from their houses in the insanitary area in houses of not less than 6s weekly rental. One of the members thought provision ought to be made for those who would be displaced at rentals nearer their pockets" The order it seems requires that 340 persons should be provided for and the mover stated in answer that other provision would be made. It is clear that in some parts of this until lately almost solely residential suburb there are slums of a bad type for while in the Monton ward of the borough the infantile mortality is 94 per 1000 it is 238 per 1000 in Irwell ward This is not to be wondered at when one sees the way in which plots of ground are covered and crowded with jerry built tenements either in defiance of building by laws or in accordance with very bad ones. The rapid extension of our towns in an unsystematic, higgledy piggledy fashion is calculated to give great trouble in the future Medical officers of health are constantly engaged in remedying conditions which ought not to have been permitted to exist and it would not be an unprofitable employment of their energies if they were allowed with the aid if necessary of architect and surveyor to prepare for such extension in the way best suited to ensure good sanitary conditions

Workhouse Infirmary for Stockport

After a long period of discussion the Stockport board of guardians at their meeting on August 7th approved and adopted plans for the construction of a new workhouse infirmary at Stepping Hill. The plans were originally made for a new workhouse but that idea being given up they have been altered so as to adapt them for a new infirmary The estimated cost is £40 000 and the plans provide for 58 beds with an administration block. A deputation is to be appointed to obtain the sanction of the Local Government Board to go on with the work.

[1] Lectures on Syphilis p. 72.

Manchester and Salford Hospital Fund

About a fortnight ago a movement was begun for the establishment of a convalescent home in connexion with the Sunday and Saturday Hospital Fund. A conference of the committee of the fund with representatives of the local medical charities took place. The proposal came from the workpeople's branch of the fund, known as the Red Cross Society It was thought that the establishment of a convalescent home would interest the people more deeply in the fund itself A scheme of this kind has been successful in Birmingham and Leeds In the former there are four such homes—one for men, two for women, and one for children—while Leeds has two Although some provision already exists here in connexion with the infirmary and other hospitals, the District Provident Society, the Cotton Districts Convalescent Fund, and other agencies, "there is ample evidence of the great need for further accommodation" It is scarcely creditable to Manchester that the statement can be made that "the workpeople in both cities are now subscribing annually several times as much as is at present obtained here," as a result apparently of the increased interest resulting from the establishment of these homes An appeal is being made to provide one home for men, with the hope that one for women may be provided later A site has been offered and some donations promised. It is said that to erect to equip, and to maintain for two years £10 000 will be required. A motion was proposed in favour of the scheme, and its supporters stated that no money would be taken from the Sunday and Saturday Fund till at least £4000 had been distributed among the medical charities The collections of the two days generally yield about £8000, and last year a sum of £7300 was distributed Naturally, therefore, objection was taken to the £4000 limit, and to secure uniformity an addition was made to the resolution that no money shall be taken for the convalescent home till at least £8000 had been given to the medical charities

August 12th

LIVERPOOL

(From our own Correspondent)

The Liverpool School of Tropical Medicine Re appointment of Major Ronald Ross

Major Ronald Ross, C B, F R.S, late I M S, who vacated the appointment that he had held in the Liverpool School of Tropical Medicine since its foundation in order to pursue another branch of scientific research work in London, has been re appointed to the post of Walter Myers lecturer to the school Steps are being taken by the school to raise an endowment for a chair of tropical medicine in the new University of Liverpool (which will shortly enter upon its corporate existence) with professional rank The lecturership was founded in memory of the late Walter Myers, who lost his life in the service of the Liverpool School of Tropical Medicine whilst on a mission to investigate yellow fever

Complimentary Banquet to the Duke of Northumberland by the Chairman of the Liverpool School of Tropical Medicine Handsome Donation to the School

The banquet given by Sir Alfred Jones, K.C M G, at the Adelphi Hotel on August 1st to the Tropical Diseases Section of the British Medical Association, to meet the Duke of Northumberland K.G, was a great success The announcement made by the host in the early part of the proceedings of the princely donation of £25 000 to the Liverpool School of Tropical Medicine by an anonymous donor was received with great applause. The speech of the Duke of Northumberland in response to the toast of his health was interesting in many ways Alluding to the amelioration of the conditions of life in the tropics, his grace said that we had arrived at a point where the warrior the diplomatist, and the colonist had done their part and it now remained for science and the medical profession to step in and to do what yet remained in that direction The bishop of the diocese (Dr Chavasse) in proposing the toast of 'Tropical Medicine' paid a flattering tribute to the unselfish work of the medical profession and said its motto appeared to be "What we know we tell and what we have we give" Interesting speeches were also made by Dr Patrick Manson, C M G, Professor Clifford Allbutt of Cambridge University, Sir William R. Kynsey, C M G, Sir William MacGregor, K C M G (Governor of Lagos), and Sir George Denton, K C M G (Governor of the Gambia), in support of encouraging in every possible manner the efforts of Major Ronald Ross and others in their efforts to extirpate malaria in tropical countries

The Mosquito Plague at Ismailia Request by the Suez Canal Company to the Liverpool School of Tropical Medicine

Sir Alfred Jones has received an important communication from Prince d'Arenberg the president of the Suez Canal Company, asking for the coöperation of the school in a concerted effort to cope with the prevalence of malaria in Ismailia. The company has made a formal request for the services of Major Ronald Ross to start operations against mosquitoes The committee of the school has at once acquiesced in the request of the Suez Canal Company and is making arrangements to enable Major Ross to proceed to Ismailia in September, when malaria is especially prevalent. Major Ross will begin by an organised campaign against malaria and will go out again later in the year to carry it through

Hospital Sunday and Saturday Funds Grants to the Charities

The total amount distributed by the committee of the above mentioned funds to the various Liverpool hospitals as a result of the year's collections was £13,600 The Royal Infirmary received £2992, the Royal Southern Hospital £2040 the David Lewis Northern Hospital £1768, the Stanley Hospital £986, the Liverpool Dispensaries, £816, the Queen Victoria District Nursing Association £816, the Infirmary for Children £816, the Eye and Ear Infirmary £544, the Hahnemann Hospital £544 the Consumption Hospital £476, the Hospital for Women £408, the Ladies' Charity and Lying in Hospital 408, St. Paul's Eye Hospital £408, the Convalescent Institution, Woolton, £340, St George's Hospital for Skin Diseases £34, &c

Proposed County Consumption Hospital by the Lancashire County Council Small pox in the County

The special committee appointed by the Lancashire county council to consider and report to the council as to the best method of appropriating the sum of £10,000 out of the county fund for the permanent celebration of the King's Coronation reports that, after a very full consideration, it unanimously recommends that the entire sum of £10,000 should be devoted towards the establishment of an institution for the treatment of cases of phthisis arising in the administrative county The public health committee of the Lancashire county council reports that during the month of June only four persons had been attacked by small pox and it was hoped that the outbreak had been successfully dealt with

Annual Meeting of the North Midland Branch of the British Dental Association.

The twenty third annual meeting of the North Midland Branch of the British Dental Association was held at Liverpool on July 24th, 25th, and 26th, under the presidency of Mr R Edwards Practical demonstrations were given by members in the Liverpool dental hospitals The President gave a reception on July 24th and the annual dinner took place at the Adelphi Hotel on the evening of July 25th July 26th was given over entirely to pleasure excursions The meeting was a most successful one

August 12th

WALES AND WESTERN COUNTIES NOTES

(From our own Correspondents.)

Cardiff Seamen's Hospital

It is nearly 40 years since H.M S *Hamadryad* was moored in proximity to the Cardiff docks and fitted up as a hospital with 40 beds for the use of the seamen who frequented the port of Cardiff, and during that period 225,000 men have been treated either as in patients or as out-patients For more than 30 years Mr William Hughes has acted as resident medical superintendent to the hospital. Four or five years ago it was felt that the usefulness of the institution would be very greatly increased by providing a building which should be constructed on the most modern principles and erected on land in the midst of the docks The late Marquis of

Bute offered to give a site for the building and £5000 provided an additional £30 000 were subscribed. Upon the death of the marquis last year it was found that he had empowered his executors to contribute any sum up to £20 000 unconditionally and the work of preparing the foundations for the building was commenced. Owing to the formation of the land this has proved both difficult and costly 131 piers having had to be constructed, and £6000 have been expended before the actual building has been begun The foundation stone of the hospital was laid on August 8th by the Marquis of Bute, who has recently attained his majority and who declared it to be his intention to take a special interest in the institution The cost of the hospital and furnishing apart from the foundations, is estimated at £24 000

Hereford Dispensary

The Hereford Dispensary was established in the year 1835 and has both a charitable and a provident department. The annual report which has recently been issued shows that in the former department 3616 patients were treated during the year In the provident department 428 households contributed in weekly pence £232, of which sum £182 were divided between the three medical officers and the balance was carried to the charity account and towards the working expenses of the institution.

The Death of Mr Joseph Reynallt James L.R.C.P. Edin M.R.C.S. Eng

The members of the medical profession in Cardiff received the news of the death of Mr J R James on August 3rd with great regret for although he had been ailing for several months it was not anticipated that his illness would have a fatal termination Mr James came to Cardiff about 25 years ago when the town was increasing in population by leaps and bounds, and has since carried on an extensive practice At one time he took an active part in the public life of the borough and was a prominent member of the town council. He leaves a widow and five children.

Exeter City Asylum

The fifteenth annual report of the Exeter City Asylum was presented at the meeting of the Exeter city council held on August 6th. It stated that 48 male and 25 female patients had been discharged cured during 1901 and that 19 male and 13 females had died during the same period On Dec. 31st 1901 there were 167 males and 205 females remaining in the institution. The maintenance rate chargeable for the Exeter patients was 11*s* 6*d* per week The committee in its report mentioned that the condition of the asylum was excellent and added an appreciative remark on the manner in which the medical superintendent performed his duties

Vaccination Expenditure

At the meeting of the Barnstaple (Devon) board of guardians held on August 1st a discussion arose over the resolution of the metropolitan boards of guardians for the reduction of the vaccination fees. The guardian took no action in the matter the chairman remarking that the conditions in the country where the public vaccinator often had to travel several miles for the purpose of vaccination were very different from those in metropolitan unions.—The Monmouth board of guardian on July 31st unanimously passed a resolution in support of the views of the metropolitan boards of guardians

August 2nd.

IRELAND

(FROM OUR OWN CORRESPONDENTS.)

Royal College of Surgeons in Ireland a Loyal Address

A DEPUTATION from the Royal College of Surgeons in Ireland waited on Earl Cadogan at Dublin Castle on August 12th and was introduced by the President, Mr L. H Ormsby The loyal address was as follows —

> To His Most Excellent Majesty Edward the Seventh of the United Kingdom of Great Britain and Ireland and of the British Dominions beyond the Seas King, Defender of the Faith and Emperor of India.
>
> MAY IT PLEASE YOUR GRACIOUS MAJESTY,—We the President Vice-President and Council of the Royal College of Surgeons in Ireland beg most respectfully to offer our loyal and cordial congratulations on the auspicious occasion of the Coronation of your Majesty and of Queen Alexandra as King and Queen of Great Britain and Ireland and of the Dominions beyond the Seas. We feel proud of being the subjects of a Sovereign who has ever been foremost in all works of charity and in efforts for promoting the comfort and alleviating the suffering of humanity not only as exemplified by the lifelong interest taken in hospital extension and efficiency but also as instanced by such movements as the housing of the working classes the Tuberculosis Congress and the Cancer Commission We rejoice that the happy event of the Coronation should have an additional splendour conferred upon it by the declaration of peace in South Africa and the permanent extension of the empire We trust the time is not far distant when Your Majesties will visit this country as Ireland's King and Queen and we venture to express our confidence that in no part of the realm would there be a deeper feeling of gratitude and welcome. As a Royal College of Surgeons we have for over a century been responsible for the training and education of a large number of surgeons who have served not without distinction in Your Majesty's navy and army We beg to assure Your Majesty of our determination to maintain the loyal and dutiful relation with your Sovereign which has always characterised the Royal College of Surgeons in Ireland We rejoice that Your Majesty has recovered from your recent illness. Signed on behalf of the council,
>
> LAMBERT H ORMSBY President.
> ARTHUR CHANCE Vice-President.
> CHARLES A CAMERON Secretary

Medical Expenses in the Belfast Union Workhouse

At a meeting of the Belfast board of guardians held recently a letter was read from the Local Government Board in reference to the recent inquiry as to the alleged excessive expenditure on medicines and appliances held by its medical inspector Dr J Smyth The Board directs the guardians to convene a meeting with a view to determine whether the medicine contractors should any longer be entrusted with the contract for supplying medicines to the workhouse It advises the guardians to impress upon their medical officers that the proper discharge of their duties involve not only skilful treatment of the sick under their charge but also the due exercise of economy in requisitioning the articles required for their patients. In addition it is to be expected that medical officers shall possess ordinary administrative capacity and a sense of responsibility in seeing that articles obtained under their signature are really necessary and are applied to the purposes for which they are ordered. The want of control over the nurses and their wasteful extravagance point, the Local Government Board says to a lax state of discipline in the nursing staff which having regard to the fact that the Belfast Workhouse Infirmary has become a large and important school for training may if not checked have far reaching evil effects and the Local Government Board requests the guardians to endeavour to provide for the proper supervision education and control of the nurses As a result of the inquiry the Local Government Board concurs with the view of its inspector Dr Smyth, that the sum of £427 11*s* was excessive and it has accordingly disallowed recoupment from the Local Taxation (Ireland) account upon this sum. The reports of the medical inspector are to be carefully considered at a special meeting of the guardians

The Smiley Cottage Hospital, Larne

Early in 1901 Mr H. H. Smiley J P Drumalis Larne county Antrim, agreed to erect an up-to-date cottage hospital for the town of Larne and since that time he has agreed to provide an endowment fund by contributing £5000 A good site with a frontage of 190 feet has been secured the plans have been prepared and have passed the urban council so that after a time the new and much required cottage hospital will be ready In recognition of Mr Smiley's princely generosity it has been decided to present him with his portrait.

The British Association.

The arrangements for the meeting of the British Association, which will begin in Belfast on Sept. 10th are now in an advanced state and it is expected that there will be a record attendance. The buildings at Queen's College have been placed at the disposal of the local committee and will form an admirable centre for those attending this scientific reunion

(FROM OUR OWN CORRESPONDENT.)

Dr Doyen's Antistaphylococcic Serum

AT the meeting of the Academy of Medicine held on July 29th Dr Doyen showed a new serum which he has just obtained and which acts he claims with efficacy in pathological manifestations due to the staphylococcus pyogenes It is especially beneficial in cases of carbuncle and boils Dr

Doyen has not yet made public the method of preparation but has published some results which are extremely encouraging One injection of 10 cubic centimetres made in the thigh, for instance, is enough in the case of a boil to bring down the temperature, to do away with the pain after the lapse of an hour, and to abort the boil altogether if it has not gone on to suppuration. If suppuration is present discharge takes place very rapidly through a small orifice, no new purulent foci form, and cicatrisation is complete at the end of 24 hours In cases of carbuncle results are remarkable and many cases have already recovered by the use of this serum together with a simple dressing moistened with some antiseptic. No incisions have been necessary Dr Doyen also reported recoveries in cases of acute phlebitis, notably one in which the ophthalmic vein was affected and where the cerebral sinus was already involved Other diseases which have rapidly ameliorated under the influence of the serum are osteo-myelitis, acute tonsillitis, and septic broncho pneumonia The action of the serum is so marked that Dr Doyen compares it to that of the anti diphtheritic serum of Behring and Roux

A Statue of Pasteur

On August 3rd a statue of Pasteur was unveiled at Dole. M Trouillot, the Minister of Commerce, presided. The Rector of the Academy of Besançon represented the Minister of Public Instruction, M Thureau Dangin represented the French Academy, and Dr Roux represented the Pasteur Institute M Ruffier (formerly mayor), M Renaud (the present mayor of Dole), M Thureau Dangin, Dr Roux, and M Mollard, a deputy, gave addresses, M Mollard drawing a parallel between Victor Hugo and Pasteur The address of M Trouilot was frequently interrupted by loud applause At the conclusion of the ceremony the school children sang a cantata in honour of Pasteur and afterwards piled palm branches at the foot of the statue In the evening a banquet was given by the municipality

Medical Excursions to the Mineral Water Stations and Sanatoriums of France

The medical excursion for 1902 will take place between Sept. 7th and 16th inclusive The places to be visited are in the Vosges and Eastern France and will be taken in the following order Vittel, Contrexéville, Martigny, Bourbonne les Bains, Luxeuil, Plombières, Gérardmer, La Schlucht, Bussang, Le Ballon d'Alsace, Salins, and Besançon. The scientific director of the excursion is, as in the three preceding years, Dr Landouzy professor of clinical medicine at the Paris Faculty of Medicine, and he will deliver lectures upon mineral water treatment. The railways will take any French medical man at a reduction of half price on his ticket from his place of residence to Vittel and to any foreign medical man from the place at which he shall set foot in France to Vittel The same reduction is allowed at the end of the excursion from Besançon to the place of departure from French territory An inclusive ticket from Vittel to Besançon costs 200 francs It includes everything—railway tickets, carriages, board, hotel expenses, luggage charges, and tips. Those anxious to join the excursion must write to Dr Carron, 2, Rue Lincoln, Paris Names must be sent in by August 25th

August 12th

NEW YORK

(FROM OUR OWN CORRESPONDENT)

Summer Work of Charity Associations of New York.

THE Children's Aid Association is one of the largest and most efficient of the associations in New York which support summer homes for poor children The large home of this society at Bath Beach accommodates thousands of children every summer and excursions are made daily there in the season for the benefit of those who can only get a day's outing The Working Girls Vacation Society gives working girls in the city an opportunity of getting a little rest and recreation in the country in summer and it also sends those who need a change to the Santa Clara Home in the Adirondacks The St John's Guild supports three floating hospitals which daily carry children and their mothers for short trips down the bay in hot weather Together these hospital ships give some 70,000 people a chance to breathe fresh sea air in July and August.—The Gilbert A. Robertson Home in Westchester affords whole families an opportunity to refresh themselves for a few weeks in the country —The Association for the Improvement of the Poor has a place at Sea Breeze, Long Island, while the Edgewater Crèche, near Port Lee, has one of the prettiest and best equipped country playgrounds and recreation places for the poor in the country

Opinions on Appendicitis in the United States

The illness of King Edward VII and the operation performed upon him by Sir Frederick Treves have caused endless discussion and much newspaper correspondence by medical men of the United States with regard to appendicitis and its treatment. The American medical profession has shown great interest in the matter and heartfelt wishes for the King's recovery have been universally expressed. Eminent authorities in this country have, however, made some severely critical remarks on the procedure adopted by his medical advisers The surgeons and physicians upon this side of the Atlantic are with singular unanimity in favour of prompt operation in all cases of appendicitis, and argue that in the case of the King the delay in operating was an error of judgment, although it must be said that the successful issue of the methods used by Sir Frederick Treves and his colleagues has to some extent silenced the advocates of immediate operation.

Committee on the Prevention of Tuberculosis

The Charity Organisation Society of New York has formed a committee on the Prevention of Tuberculosis, consisting of Dr E L Trudeau, Dr Lederle, New York City, commissioner of health, the Hon. Horner Folks, head of the city's department of public charities, and several other members, equally well known, 11 of whom are physicians. The objects of this committee have been formulated in part as follows in a statement made by the Charity Organisation Society (1) the promulgation of the doctrine that tuberculosis is a communicable, preventable, and curable disease, (2) the dissemination of knowledge concerning the means and methods to be adopted for the prevention of tuberculosis, (3) the advancement of movements to provide special hospital, sanatorium, and dispensary facilities for consumptive adults and scrofulous and tuberculous children among the poor, and (4) the initiation and encouragement of measures which tend to prevent the development of the various forms of tuberculous disease

AUSTRALIA

(FROM OUR OWN CORRESPONDENT)

The Plague

AT a meeting of the Board of Health held at Sydney on July 1st it was decided to declare Sydney free from plague, as more than 10 days had elapsed since the last case was reported There are 16 patients suffering from the disease in the Coast Hospital but they are all recovering As the plague has disappeared from Sydney Mr T A. Grieves has retired from the service of the Board of Health At the outbreak of the first epidemic he was appointed to investigate reported cases and he has diagnosed most of the cases that have occurred, and his services and expert knowledge have elicited the warmest eulogies from Dr Ashburton Thompson, the President, and Dr F Tidswell, the chief medical officer of the Board of Health. On July 1st Dr B B Ham, the Public Health Commissioner for Queensland, in reply to a deputation of ship owners, stated that as the port had been free from plague for 31 days he intended to advise that the plague regulations be rescinded

The Friendly Society Difficulty

At a recent largely attended meeting of the Friendly Societies' Association of New South Wales the following motion was proposed and after a long and general discussion was carried by 20 votes to 11 —

> That the Australian Natives' Association be requested to retire from the Friendly Societies Association as their aims and objects are inimical to the interests of the association

This is a very severe reflection on the position of the Australian Natives' Association, and a great triumph for the medical profession in New South Wales. Leading officials of the Australian Natives' Association in Victoria commenting on the action of the friendly societies in New South Wales attribute it to jealousy, to the intimidation of the medical profession, and to the indiscretion of members of the New South Wales Australian Natives' Association in dealing with unimportant public and political questions.—In Victoria friction has arisen between the Ancient Order of Foresters and some of the medical officers of their lodges and it has been decided to establish a medical institute for the benefit of members of friendly societies in Fitzroy Collingwood, and Carlton, very thickly populated suburbs on the north east of Melbourne. A constitution and rules for the institute have been drawn up. The surgeons to the institute are to devote their whole time to the members and are to be paid at the rate of £300 per annum each and £6 per annum for every 10 or proportion of 10 members over 500 registered on their lists provided that the total number shall not exceed 1000. The proposed institute was discussed by the Carlton branch of the Australian Natives Association but the question was not put to the vote. It was stated that the reason for establishing an institute was an attempted boycott of a lodge in Fitzroy by medical men which would have been successful but for the action of one medical man who, in spite of threats from his fellow members of the Medical Defence Association, went to the assistance of the lodge The facts are as follows. Court Friar Tuck of the Ancient Order of Foresters resolved to reduce its payment to the court surgeons from 15*s* per annum per member to 13*s* and gave the surgeons a month s notice to terminate existing agreements. These surgeons were all members of the Carlton, Collingwood and Fitzroy Branch of the Medical Defence Association of Victoria and the matter was discussed at a meeting of the branch and the members of the branch present at the meeting decided to decline to accept the position of surgeons to the court at less than 15*s* *They also subsequently obtained promises from all the other* members of the branch to do the same Amongst those who promised was Mr Peter Lynch of Carlton. However when applications were called for Mr Lynch applied and was appointed surgeon to the court at 13*s* The secretary of the Carlton, Collingwood, and Fitzroy Branch of the Medical Defence Association accused Mr Lynch of having acted in a manner calculated to bring discredit on the association." The council of the Defence Association after hearing much evidence and holding many *meetings excluded Mr Lynch from the association.* It may be observed that the reason that the members of the branch resisted the action of Court Friar Tuck was that it is one of the largest most powerful and wealthiest lodge in the district, having 306 members on its roll and a credit balance of over £5000 in addition to a benevolent fund and last year paid away £9379 in medical benefits

A New Hospital for the Northern Suburbs of Sydney

The foundation stone of a new hospital for the northern suburbs of Sydney was laid on June 13th by the Governor of New South Wales The institution is close to St. Leonard s railway station and when completed will contain 200 beds. The pavilion system has been adopted, running on an axial line bearing north north-east so that all aspects will have the sun at some time of the day The completed scheme comprises 13 blocks that for administrative purposes being in the centre. Each ward to hold 20 beds, will be 92 feet six inches by 26 feet. It is proposed at first to erect two large wards and two isolation wards with a total of 44 beds. His Excellency in replying to an address from the trustees said that he would take the earliest opportunity of obtaining His Majesty s consent to designate the in titution the Royal North Shore Hospital."

Proposed Changes at Melbourne Hospital

At the meeting of the committee of the Melbourne Hospital held on June 24th a conference was held with the honorary medical and surgical staff as to certain proposed changes in the method of appointment tenure and number of the honorary staff and the increase of the accommodation concerning which correspondence had passed between the committee and the staff At present, as is only too notorious the whole honorary staff is elected by the subscribers to the hospital every four years the method of election giving rise to great scandal and being very degrading to the candidates. There is no retiring age. The work of the hospital especially on the surgical side and as regards clinical in truction has greatly increased but the number of the staff and the accommodation remain as they were originally and the buildings are out of date The completion of the new fever hospital ought to relieve the Melbourne Hospital of some of its cases and the committee proposed to erect new ward on the site of the present tents for infectious cases. As stated previously in these columns the Board of Health objects to these proposals unless they embrace a scheme for the gradual rebuilding in modern style of the whole hospital. All these questions were then referred to the staff who carried the following resolutions —

1 That the retiring age for indoor physicians be 65 and for indoor surgeons 60 but that, as regards the present indoor members, their appointment be for 13 years from expiry of present term of office in the case of those members who shall not have reached the age of 65 as indoor physicians and the age of 60 as indoor surgeons

2. That vacancies for the indoor staff be filled by promotion from the out-patient staff by seniority according to hospital rule.

3 That vacancies in the out-patient staff be filled by th subscribers

4 That the number of beds be increased

5. That there be five in-patient physician and five in-patient surgeons and that the number of the out-patient staff be the same as at present.

These were presented to the committee and explained by the chairman of the staff who pointed out that the present system of election was a scandal and militated against good work by the staff. The hospital was the clinical school of the largest medical school in Australia, and to maintain a high standard in the training of students and afford proper facilities for medical teaching the institution required remodelling and if it did not keep abreast of the times the medical school would have to seek other institutions to carry on the clinical part of the work. The matters were adjourned for further consideration by the committee.

Women s Hospital Melbourne

Dr Martell, who took the position of resident medical officer of the Women s Hospital Melbourne has resigned as she found herself unable to carry out the duties single-handed. The resignation was accepted with deep regret and Dr Martell was personally thanked for her good work. A special meeting is to be held to consider the position The honorary staff wrote to the committee regretting that [a want of agreement existed between the staff and the committee and that it was due to the fact that in professional matters their expert advice had not received the recognition from the committee which was its due. It was re olved to ask the staff to point out any instances to support its statements. The financial position of the hospital is not quite satisfactory The receipts had fallen short of those for the previous year by £1236 and the expenditure had increased by £671. Public subscriptions had fallen off and the Government grant was less The increased expenditure was due to the greater cost of provisions.

Sydney Hospital

Plans for a new casualty room and large waiting room are being prepared for the Sydney Hospital. They are to be one-storeyed and situated at the back of the hospital with an entrance from the Domain, and are e timated to cost about £1500

Action by a Hospital Surgeon for Compensation for Wrongful Dismissal

A case of some interest to the medical profession was recently tried in Sydney before Mr Justice Owen and a jury Dr John Krueger Kelmar a duly qualified medical practitioner was appointed in May 1901, by the committee of the Wyalong Hospital as medical officer at a salary of £8 8*s*. a month for the balance of the year 1901 According to the by laws the committee had power in the case of gross misconduct on the part of the medical officer to discharge him without notice. By a resolution of the committee on Oct. 31st the plaintiff Kelmar was dismissed under the following circum tances The hospital had private rooms for paying patients. In June a boy was injured at some works and at the request of his employer was placed in a private room and was there 14 weeks, during which time the committee charged 30*s* a week for his maintenance. After the boy left Dr Kelmar sent *in an account to his* employer for £44 2*s* pointing out the nature of the services rendered. The employer complained to the committee that the charge was unju t. The committee decided against Dr Kelmar and [illegible] him He claimed £200 The jury decided in favour of Dr Kelmar and awarded him £69 2*s* being £19 2*s* balance of salary and £50 damages for di missal.

Haab Electro-Magnet for the Victorian Eye and Ear Hospital

Th tru tees of the Edward Wilson bequest for charitable purposes have presented the Vic rian Eye and Ear Hospital with a Haab electro-magne for the extraction of foreign metallic bodies from the eyeball.

The Right of an L S A. to Practise as a Pharmaceutical Chemist

Last year reference was made to a case in which Mr Honman, L.S A., was charged with carrying on the business of a chemist while not registered under the Pharmacy Act The magistrates dismissed the case, holding that it had not been proved that Mr Honman was carrying on a chemist's business within the meaning of the Act. The secretary of the Pharmacy Board obtained an order to review the magisterial decision The case was heard by the Chief Justice He ruled that Mr Honman's qualification of L S A. entitled him to practise as a chemist in England. By the Medical Act of 1858, which extended to Australia, medical men were entitled to practise according to their qualifications The rights given by that Act were not cut down by the Victorian Act and a Licentiate of the Society of Apothecaries of London was entitled to carry on business as a chemist without registration under that Act The magistrates' decision was right though their reason for it was wrong and the order to rescind was discharged with costs

Appointments

Dr T J M Kennedy, has been appointed port health officer at Geelong —Mr J T Brett has been appointed a member of the Medical Board of Victoria, in place of Dr T Rowan who has gone to South Africa.—Mr F M Harricks has resigned his position as surgeon to out-patients at the Alfred Hospital, Melbourne.—Dr W A. Wood has been appointed lecturer on Art Anatomy to the School of Art, Melbourne —Dr L. G Balfour and Mr Farmer have been appointed anæsthetists to the Melbourne Hospital

Obituary

Dr L G Mallam of Armidale, New South Wales, died from pneumonia on June 29th. Deceased was born in Maitland 44 years ago and went to Armidale with his father, who was a chemist, in 1865 He was educated primarily in the Armidale Public School, after which he went to Sydney and then proceeded to Edinburgh, taking the degree of M B in 1884 He had been practising in Armidale for 18 years and was one of the medical officers of Armidale Hospital, he was also medical officer of the Guild Lodge. He was a member of St Peter's Cathedral Council and also of the public school board He leaves a wife and several young children.

July 5th

Obituary.

JAMES THOMAS WARE, F R.C S ENG

WE regret to announce the death of Mr James Thomas Ware at his residence, Tilford, near Farnham, Surrey, on July 30th. Mr Ware, who was born 85 years ago, was the eldest son of the late Mr Martin Ware of Tilford and of his wife Anne, the younger daughter of the Rev Thomas Tayler of Tilford Surrey, and Whitlenge, Worcestershire Both Mr Ware's father and grandfather, Mr James Ware, were eminent as surgeons and oculists, the latter being a Fellow of the Royal Society and one of the founders of the Medical Society of London

Mr Ware entered as a student at St. Bartholomew's Hospital in 1835, and subsequently became house surgeon and a governor of the hospital He also studied at Berlin, Vienna, and Paris While at St. Bartholomew's Hospital he took an active part in founding the Metropolitan Convalescent Institution, now so well known for its important and beneficial work carried on at Walton (Surrey), Broadstairs, and Highgate. One of his fellow students, Theodore Monro, being struck by the necessity of fresh air and proper kind of treatment for a poor girl in the hospital, whose leg had been amputated and who was about to be discharged though in a state of great weakness, consulted Mr Ware and a few other fellow students and friends and determined to establish a home for convalescents in the country The result was that they founded what is now known as the Metropolitan Convalescent Institution. At the time of which we are now speaking—about 60 years ago—there was no such thing in the country as a convalescent home. This institution was the first, the pioneer of the large number of these useful and beneficial homes which are now spread over the country For many years Mr Ware took an active part in the management of this charity as a member of the committee, and especially as one of the surgeons, and when he was unable to assist in this work he became one of its vice-presidents

When Mr Ware was still a young man his health failed for a time and as a consequence he relinquished the medical profession, though his knowledge and skill in it were of great use to him in after life, especially as the squire of a country village and in reference to his work as a Poor-law guardian. On retiring from the profession Mr Ware settled on the family property at Tilford, where his unvarying kindness and wise help were highly appreciated by his neighbours. After a time he became one of the guardians of the Farnham Union and was elected chairman, in which office his ability, character, and wisdom were most valuable and much appreciated. *For many years* Mr Ware was churchwarden of Tilford church, the foundation stone of which was laid by his father About 19 years ago Mr Ware met with an accident to his knee from which he never recovered For the last two years he had been confined to his bed and in the early morning of July 30th he passed peacefully away The funeral took place on August 2nd at Tilford church and was attended by many of his neighbours, friends, and tenants. Mr Ware was never married

Physiology only —Mr Arthur Frank Palmer, Cambridge University and Middlesex Hospital.

FREEMASONRY —The American Ambassador, Mr Choate on Friday August 8th unveiled at Freemasons' Hall an excellent portrait of George Washington which had been presented to the United Grand Lodge of English Freemasons by Mr Henry S Wellcome, an American resident in London whose name is known to members of the medical profession The portrait which is full length, is the work of an American artist, Mr R. Gordon Hardie, who was at great pains to ensure the correctness of the costume and of the masonic regalia in which the most distinguished of all Americans is depicted. The Earl of Warwick, Deputy Grand Master occupied the chair and addressed a few words of greeting to Mr Choate, which were heartily endorsed by the large company present. Mr Choate after unveiling the portrait gave an interesting appreciation of the character of Washington

UNITED KINGDOM POLICE SURGEONS' ASSOCIATION —A meeting of this association took place at Manchester on July 30th Dr H. W Oulton of Dublin (Vice-President) occupied the chair The question of the fees of medical witnesses and the attitude of the Home Office in respect thereto was discussed Mr Frederick W Lowndes, M.R.C.S. Eng of Liverpool (honorary secretary), and Mr H. Nelson Hardy F.R.C.S Edin of London (treasurer) described the nature of the evidence which they had given before the Departmental Committee of the Home Office. Criticism was also passed upon the action of the Home Office the Home Secretary having described as discreditable" the attitude of the medical men at Bungay who refused to examine a police case which involved their giving evidence at unremunerative rates.

IRISH MEDICAL SCHOOLS' AND GRADUATES' ASSOCIATION —The summer general meeting of the above association was held at the Owens College Manchester on July 30th In the absence of the President (Sir Philip Crampton Smyly) the chair was occupied by Dr Richard Fegan (Blackheath). Among the other members present were Dr P S Abraham (London) Mr J Chestnutt (Howden) Dr W Douglas (London) Dr Stanley A. Gill (Formby) Dr F S Gramshaw (Stillington) Mr T Adrian Greene (Ennis) Dr J Mills (Ballinasloe) Dr A. Morton (Halifax) Dr J Goodwin Shea (Chesterfield) Dr O T Woods (Cork), and the honorary secretaries, Mr J Stewart (Sneyd Park) and Dr J H. Swanton (London) The council reported that Wednesday Nov 26th had been fixed for a banquet to be given to the Commander in Chief by the association at the Hotel Cecil London, and that the Countess Roberts and the Ladies Roberts had also accepted invitations to dine with the association on that evening The council also reported that a considerable accession to their members had been made since the annual general meeting and that there was a prospect of the total number on the roll reaching 1000 members before the date of the banquet to Earl Roberts A vote of thanks to the council of the Owens College for the use of the room terminated the proceedings

DURHAM UNIVERSITY COLLEGE OF MEDICINE, NEWCASTLE UPON TYNE.—During the last 12 months there has been a large increase in the number of specimens examined in the Bacteriological Diagnosis Department of the College of Medicine, Newcastle upon Tyne Some of these examinations have been made for medical practitioners others by special arrangement. for the county councils of Northumberland and Durham the Guisbro combined district councils of the North Riding of Yorkshire, the town councils of Newcastle and Sunderland and the Royal Infirmary and the Hospital for Sick Children Newcastle The total number of specimens examined in the laboratory during the year ending May 31st, 1902, amounts to 1009 as compared with 595 during the preceding 12 months The different kinds of examinations carried out were as follows 428 samples of sputum from suspected cases of phthisis were examined for tubercle bacilli which were found in 215 cases 233 specimens of blood were examined from suspected cases of enteric fever by Widal's method, a positive result being obtained in 103 and 228 swabs from suspected cases of diphtheria were examined for the bacilli which were found in 99 specimen 16 specimens of pus were examined the pneumococcus was found in three streptococcus pyogenes in two, staphylococcus pyogenes albus in two, staphylococcus pyogenes aureus in two gonococcus in one and bacillus coli communis in three 10 samples of urine were examined for tubercle bacilli, which were found in three Eight specimens of blood in suspected cases of anthrax were examined positive results being obtained in six One specimen of serum from a suspected case of malignant pustule was examined and anthrax bacilli were found Three specimens from suspected cases of tetanus were examined with negative results. Two specimens from suspected cases of glanders were examined with negative results. Four inoculations were made from the blood of a lamb with louping ill with negative result. Two specimens of milk were examined (one for tubercle bacilli and one for septic organisms). Four samples of ice-cream were examined in one of which as many as 3,120 000 bacteria were found in one cubic centimetre. 70 samples of water were examined quantitatively for bacteria.

Parliamentary Intelligence

NOTES ON CURRENT TOPICS

The Session.

AFTER sitting for nearly seven months Parliament has adjourned until Thursday Oct. 16th The rule is to have prorogation about this period of the year but it happens that the work of the session is far from completed and consequently adjournment until the autumn has been rendered necessary It is clearly understood that the main business when Parliament reassembles will be the Education Bill and the London Water Bill both of which measures are at present in the committee stage So far the only legislation of special interest to the medical profession passed this year has been the Midwives Act.

HOUSE OF LORDS.

THURSDAY AUGUST 7TH

Sickness on Board a Transport

Earl CARRINGTON raised the question of the alleged overcrowding of the hired transport *Drayton Grange* during her voyage from Durban to Australia and consequent sickness among her passengers who consisted of Australian troops.—The Earl of HARDWICKE intimated that the Secretary of State for War was prepared to make inquiry into the subject He explained that the *Drayton Grange* was a cargo ship of 8000 tons She was surveyed by the naval authorities at the Cape and passed for 40 officers and 2000 men each man having a hammock berth and the usual hospital accommodation being provided The principal transport officer in South Africa and the principal medical officer at Durban denied categorically that there was any overcrowding and the latter further stated that all the troops embarked in good health and that no case of infection was on board The actual numbers embarked at Durban were 41 officers, seven warrant officers, and 1934 men As there appeared to have been an outbreak of measles on board the necessity for extemporising isolated quarters for the patients might have led to some inconvenience.

HOUSE OF COMMONS

TUESDAY AUGUST 5TH.

Medical Test for Army Candidates

Sir JOHN STIRLING-MAXWELL asked the Secretary of State for War whether he was aware that Mr H H Fleming of Glasgow a university candidate for the army having been pronounced physically fit for a commission by a medical board in Edinburgh in July 1900, was in October 1901 rejected by the medical board who made the final examination for a congenital defect which was discovered and passed by the first board; and whether in view of the fact that the inconsistency of the two boards cost Mr Fleming 15 months of time and £200 of money the Secretary of State would undertake that candidates would be rejected in future for congenital defects at the preliminary examination if they were to be rejected at all —Mr BRODRICK replied: There was no inconsistency between the reports of the two boards as the candidate's health had become worse in the interval

WEDNESDAY AUGUST 6TH

The Meal Intervals of Post Office Workers

Sir WALTER FOSTER asked the Secretary to the Treasury as representing the Postmaster-General whether his attention had been called to a resolution passed by the postal and telegraph employés attached to the Birmingham Post Office protesting against the withdrawal of intervals for meals on certain divided attendances and whether in view of the recommendations of the medical department of the General Post Office that overfatigue and long fasting should be carefully guarded against he would modify the regulations so as to prevent the employés being compelled to take two meals between 2 P.M. and 4 P.M., or else undergo a fast for a period exceeding six hours daily with the liability to be retained on duty one hour further before being permitted to partake of refreshment —Mr AUSTEN CHAMBERLAIN replied The Postmaster General has seen the resolution in question He understands that it refers to a desire of the staff that intervals for meals should be allowed in the case of attendances not exceeding four hours in duration, such as from 10 A.M. to 2 P.M.

followed by one from 4 P M to 8 P M In the case of duties arranged in this manner it does not appear to the Postmaster-General that any interval for meals is required If however the attendance is prolonged to four and a half hours or upwards an interval of 15 or 20 minutes is given

The Ventilation of the House of Commons

In the course of the discussion on the Appropriation Bill Mr WYLIE called attention to the state of the atmosphere in the House on occasions when there was a large attendance of members and of the public He insisted that it was most deleterious and that evil results followed, and he recommended the adoption of electric ventilating fans

THURSDAY, AUGUST 7TH

Buildings on Disused Burial Grounds

Mr BRYCE asked the Home Secretary whether his attention had been called to several recent cases in which faculties had been granted by the Consistory Court of the diocese of London for the erection of buildings upon disused burial grounds in London whether it was the fact that the buildings so permitted by these faculties were not enlargements of a church but other buildings, in respect of which no exception was made to the general prohibition of the erection of buildings on such burial grounds contained in the Disused Burial Grounds Act 1884, whether any and what steps could be taken to secure the due observance of the provisions of the last-mentioned Act in order that these open spaces might be reserved for the use of the public or whether if the law was defective, he would take any steps to have it amended —Mr RITCHIE replied: I have referred to the chancellor of the diocese and am informed by him that in all cases in which he has granted faculties for the erection of buildings upon disused burial grounds he was satisfied that the buildings were enlargements of a place of worship within the meaning of the Disused Burial Grounds Act 1884 It does not appear on the facts before me that an amendment of the law is required There is a right of appeal from the Consistory Court to the Court of Arches and thence to the Judicial Committee of the Privy Council besides the procedure by writ of prohibition if the ecclesiastical court exceeds its jurisdiction I may add that I understand that the chancellor of the diocese will make it a rule of court that due notice of applications for faculties of this kind shall be given to the London County Council who have powers under the Disused Burial Grounds Acts

Hansom Cab Accidents in London

Sir HOWARD VINCENT asked the Home Secretary if the returns of the Public Carriage Department of the Metropolitan Police afforded any information as to the number of accidents last year in hansom cabs and if by legislation or otherwise some improvement could be brought about in the arrangement of the window so as to secure greater safety to the passenger and bring it as in Manchester under the latter's control instead of that of the driver — Mr RITCHIE replied: The number of accidents in hansom cabs brought to the notice of the police in the course of last year (1901) was 94 Of this number 39 were caused by collisions 43 from the horse falling and 12 from various causes such as the breaking of harness, from a wheel breaking &c. In no case reported to the police does it appear that injury was caused by the arrangement of the window and though the present vehicle is doubtless not perfect it would hardly appear that any legislation is demanded in the direction suggested in the question If any effective substitute for the present window is suggested the Commissioner of Police would have it brought to the notice of proprietors as is invariably done when attention is drawn to desirable improvements The adoption of these improvements however is a matter for the makers and the owners of these convenient and popular vehicles who would promptly respond to any public demand for alteration Every care is taken to see that the licensed hansom cabs are fit for use

FRIDAY AUGUST 8TH

Milk Adulteration Prosecutions

General LAURIE asked the President of the Local Government Board whether his attention had been called to the report of the public analyst of the borough of Paddington of March 25th last in reference to the difficulties experienced by local authorities in conducting prosecutions for adulteration of milk and whether such amendments of the law would be proposed by him as would enable local authorities to conduct such prosecutions without being penalised in costs —Mr LONG replied: My attention has not been drawn to this report but on receiving a copy of it I will give consideration to the matter

Ear Trouble in the Hanwell Schools

Mr FLOWER asked the President of the Local Government Board whether he would state what steps if any were being taken to carry out the suggestions in the report on Mr A H Cheatle s examination of 1000 of the children at the Hanwell Poor law Schools which had been prepared by the medical officer of the schools —Mr LONG replied: I am informed that a committee of the managers will meet this afternoon to receive a report of the medical officer of the schools as to special treatment of the cases of ear trouble and that steps are being taken to obtain permission from the parents to operations being performed in cases in which surgical treatment is required As I stated in reply to a question last month the children suffering from adenoids have been receiving surgical treatment

Treatment of Feeble minded Paupers

Lord HUGH CECIL asked the President of the Local Government Board whether his attention had been drawn to the difficulties attending the treatment and care of feeble-minded paupers in workhouses and whether he would consider the propriety of appointing a departmental committee to inquire and report on the matter —Mr LONG replied: The case of the feeble-minded in workhouses has been brought before the Local Government Board and at the request of the National Association for promoting the welfare of persons of this kind my predecessor obtained some statistics which were communicated to the association I shall be happy to consider any further representations which may be made on the subject but I am not at present prepared to say that it would be desirable to appoint a departmental committee with regard to it.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o clock on the Thursday morning of each week, for publication in the next number*

BLEASE, ARTHUR TORKINGTON, M R C S, L R C P Lond M B, Ch.B Vict has been appointed Senior Resident Medical Officer to St. Mary's Hospital for Women and Children, Manchester

CLAY, DAVID LLOYD, M R C S L R C P Lond has been appointed Public Vaccinator for the District of Otaki New Zealand

ELLIS, ALFRED P B late Captain in the Medical Department, S.A.C., has been appointed a Plague Medical Officer for the Punjab India.

FINN P T, L R C.P Edin L.R C S Edin L F P S Glasg, has been appointed Certifying Surgeon under the Factory Act for the Ashwick District of Somersetshire

HARDING NORMAN E M B Ch B Edin, has been appointed Second House Surgeon to the East Suffolk and Ipswich Hospital.

HARVEY, ALFRED, M B Lond. M R C S L S A has been appointed Medical Officer to the Southmead Workhouse by the Barton Regis Board of Guardians

HOOLE, JOHN M R C S Eng L S A Lond, has been appointed Medical Officer and Public Vaccinator to the Hartington District of the Ashbourne Union

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—Assistant House Surgeon. Also Assistant House Physician. Appointment for six months, with honorarium at rate of £75 per annum, board, lodging, and washing.

THE Chief Inspector of Factories, Home Office, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory Act at Harrogate.

Births, Marriages, and Deaths

BIRTHS.

ATTLEE.—On August 6th, at 58, Brook-street, London, W., the wife of John Attlee, M.D., of a son.

HASTINGS.—On August 8th, at 415, Mile End-road, E., to Edwin Birchall Hastings, M.D., and Theresa Hastings, a daughter, Anna Birchall.

HARDYMAN.—On August 11th, at Pulteney-street, Bath, the wife of George Hardyman, M.B., F.R.C.S. Edin., of a son.

HENSHAW.—On August 8th, at Priory-terrace, Kew-green, Surrey, the wife of H. W. Henshaw, M.R.C.S., L.R.C.P. Lond., D.P.H., of a daughter.

MARSHALL.—On August 7th, at Ashcroft-villas, Cirencester, the wife of Howard Marshall, M.B. Cantab., of a daughter.

DEATHS.

KELLY.—On August 5th, Charles Augustus Kelly, M.R.C.S. Eng., L.R.C.P. Edin., Civil Surgeon to H.M.'s Forces at York, aged 46.

NEAL.—On August 10th, at his residence, St. Cross, Sandown, Isle of Wight, James Neal, M.D. St. And., aged 66 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents

INFLUENCE OF INJECTIONS OF OXYGEN ON INFECTIOUS DISEASES.

WE have received from Dr. Ermanno Palombi of Macerata, Italy, a small pamphlet containing a preliminary announcement relative to some observations which he has made on the effects of injections of oxygen. He commences with a reference to the recent injection of oxygen into the veins of dogs by Gärtner and into the human veins by Mariani and Maragliano of Genoa. Dr. Palombi has for 10 years been occupied with this question, chiefly in the direction of supplementing impaired pulmonary respiration by means of injections of gaseous oxygen into the femoral veins, the peritoneum, or the subcutaneous cellular tissue. He also tried peroxide of hydrogen and after many experiments he succeeded in preparing an "oxygenated serum" which he found had the effect of considerably retarding and diminishing the effects produced by inoculation with various pathogenic materials, such as pus, tuberculous sputum, and diphtheritic membrane.

A CASE FOR DIAGNOSIS.

To the Editors of THE LANCET.

SIRS,—I should be deeply grateful if you or any of your subscribers would suggest some treatment which would be beneficial in the following tedious case. I have given all the ordinary drugs generally administered, but with no satisfactory or beneficial result. I have likewise given carbolic acid, creasote, and other intestinal disinfectants internally, combined with injections of boric acid solutions mixed with oatmeal water. The case in question is that of a man aged 60 years who has been a hard drinker for 20 years. His bowels have always been irregular, diarrhœa and constipation alternating with each other. *Lately the attacks of diarrhœa have been frequent* with marked tenesmus and evacuation of mucus mixed with blood. Every two or three days the patient is seized with violent griping pains and the only thing that offers relief is the above rectal enema, although unaccompanied by any motion except mucus. To my mind there is no doubt that the case is one of ulcers situated at a point somewhere between the splenic flexure and anus. Any hints as to further treatment will be much appreciated. Thanking you for inserting the above,

I am, Sirs, yours faithfully,

August 12th, 1902. A SUBSCRIBER.

HYGIENE FOR HAIRDRESSERS.

"To my horror," writes a correspondent, "I discovered yesterday morning that I had a patch of ringworm at the back of my head. The only probable source of infection is a barber's shop where for about a year I have had my hair cut. It is a fairly clean and well appointed establishment, but so far as I am aware no disinfection *of brushes and instruments is ever attempted*." The subject is one of considerable interest to medical men and we refer our readers to a brief article which appeared in our columns on Feb. 8th, 1902, p. 419. Our unfortunate correspondent is entitled to sympathy; his very disagreeable acquisition is one to which most of us are exposed through the tyranny of fashion which has tabooed the wearing of long locks, save for spring poets. As a rule barbers regard antisepsis and disaster as convertible terms, but it ought to be possible to overcome this prejudice. The difficulty is to convince them that the antiseptic process can be carried on without excessive damage to their stock-in-trade. Steel instruments can easily be made safe by singeing in the flame of a spirit lamp; but with brushes the case is different. Immersion in an antiseptic solution brings on premature decay of the hair; while the employment of sterilised steam not only entails great expense but also leads to the ungluing of backs and the softening of cement. If combs and brushes entirely composed of metal were available the question of disinfection would be simplified, but so far such goods have not found favour. In the June number of the *Archives de Médecine Navale*, p. 478, Dr. Couteaud, a French naval surgeon, describes a simple method of ensuring the disinfection of hair and shaving brushes without injury to them. All that is required is a *formolateur Milia*, which consists of an alcohol vaporiser in connexion by means of a glass and rubber tube with a so-called "hygienic bucket" (*seau hygiénique*). A single paraformic pastille costing a trifle gives out a formaldehyde vapour which will render the contents of the bucket perfectly sterile in about 12 hours. In order to test the trustworthiness of the apparatus Dr. Couteaud instituted a series of experiments by which he was convinced that it was scientifically perfect. If hairdressers and barbers were wise in their generation they would adopt something of the kind and place proofs of their hygienic up-to-dateness before the public. It would undoubtedly lead to a large increase in the number of their customers. In addition to the appliances already mentioned it is possible in the same way to disinfect not only combs and brushes but also syringes, catheters, and other hollow instruments that ordinarily are very hard to keep absolutely clean. The *Milia* should also prove invaluable to dentists.

THE "Y" FUND

Surgeon General H S Muir begs thankfully to acknowledge additional donations towards the above Fund from Surgeon Majors Beevor (Scots Guards), Rayner (Royal Horse Guards), and D Elcum I M S (retired) Lieutenant W M Houston, I M S Brigade-Surgeon C H Browne A M D (retired), Dr Thomas and Dr Nash (South Africa) A. B C" "D E F," and "X Y Z" (anonymous from South Africa) and the following officers R.A.M C: Colonels R Exham and H Martin Lieutenant Colonels R J S Simpson E O Wight and R H Sawyer Majors Mathias J M Nicholls, and J Donnet and Captains T McDermott Austin O Fflahertie, W E Hardy, A. H Young and J H Power The fund now amounts to £525 It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly "handing on to *confrères*) Should any reader of The Lancet desire further particulars with a view to expressing *practical sympathy* a copy of the letter will be forwarded on application to Surgeon General Muir 26, Kensington-gardens terrace, Hyde Park, London, W

A SIMPLE INHALER.

To the Editors of The Lancet

Sirs —I should like to bring under your notice an idea for a portable inhaler which I have found very useful Get a common cherry wood cigarette-holder and pack it with absorbent wool on which can be placed a few drops of creasote or eucalyptus oil or any other drug This can be used in the street or elsewhere without attracting attention and furthermore, its cost need not exceed 1½*d*.

I am, Sirs yours faithfully
P H Parsons L R C P Edin,
Late Resident Medical Officer, Manchester Chest Hospital
August 11th 1902

FOREIGN MEDICAL LITERATURE

To the Editors of The Lancet

Sirs —In answer to the query of "A. C C" regarding foreign medical literature in your issue of June 14th I beg to inform him that medical subscription libraries exist in Germany to my knowledge: (1) M Boas Berlin N W Karlstrasse 25, and (2) Johannes Alt, Frankfurt a. M. Possibly either one or the other of these two may be able to accommodate him

I am Sirs yours faithfully,
S A. Philippi M D
Bad Salzschlirf August 9th 1902.

THE BABY FARMER AGAIN

At the Westminster Police-court on August 12th Elizabeth Glasse was charged with neglecting nurse children and with the manslaughter of an illegitimate infant aged eight months at Seaton-street Chelsea. The coroner s officer for Chelsea and an inspector of the National Society for the Prevention of Cruelty to Children said that in the room occupied by the accused they found two infants aged respectively eight months and 12 months partially covered with rags and chaff infested with vermin and ravenously hungry Another inmate of the room was a woman suffering from the effects of alcoholism Both this woman and the infants were removed to the Poor law infirmary where the younger child afterwards died Mr Sheil committed the prisoner for trial on the charge of neglect she being already committed by the coroner for manslaughter

MEDICAL EXAMINATIONS FOR THE CAPE MOUNTED POLICE

To the Editors of The Lancet

Sirs,—Can any of your readers inform me whether it is any use for a young man suffering from secondary syphilis to go to London to pass the Medical Board for the Cape Mounted Police? or would the existence of syphilis absolutely disqualify?

I am, Sirs, yours faithfully
Mercury
August 12th 1902.

THE LAW FUND

TRUSTEES: THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON

Dr. R. Paramore writes to us as follows from 2, Gordon square, W C:—"A meeting of the friends and sympathisers of Dr W T Law will be held at the Holborn Restaurant London W C on Friday afternoon August 29th 1902. The chair will be taken by Sir William Church The presentation of the gifts from members of the medical profession will be made to Dr Law In the meantime the fund will remain open for the reception of any contributions from all who are interested in the success of the movement" Dr Paramore adds his belief that with the exception of the case of Dr Cullingworth which was so generously responded to by the medical profession no more deserving case has appeared for the universal sympathy of the profession If the prosecution had succeeded there would have been no limit to these vexatious proceedings of actions being brought by ungrateful patients Cheques and postal orders should be made payable to the Law Fund and crossed London and County Bank, Holborn, W C "and sent to me, and I will most gladly acknowledge all donations however small The following additional subscriptions have been received by Dr Paramore:—

THE REWARD OF MERIT

The *Westminster Gazette* of August 12th publishes the following "from the advertising columns of a provincial paper"—

> A Nobleman, travelling abroad, will be glad to hear of a fully qualified Medical Man to accompany him who is an expert in passing a bougie into the middle ear, and the treatment of ingrowing toe-nails terms, food and out of pockets an M.D preferred evening dress and Church of England.—Address, &c.

Our contemporary has omitted to give the nobleman s address so that we cannot supply him with a free advertisement to the extent that we should like to do In the overcrowded state of the medical profession this appointment may offer a chance not to be missed, but this largely depends on the personality of the nobleman For though peers are technically equal, there are peers and peers Not every M.D can command the society of a first-class nobleman, and with "food and out of pockets" thrown in the post might be everything that a gentleman, a member of a learned profession and the possessor of a suit of dress clothes ought to expect But it might not be such a post, and the nobleman might turn out the sort of person with whom decent people do not care to foregather From the character of the advertisement we suspect the latter, or a hoax.

SOME VIEWS ON ANTITOXIN

To the Editors of The Lancet

Sirs —I notice that J J Lawrence A.M M D, editor of the *Medical Brief*, in a recent issue of that journal states that antitoxin is the greatest delusion of modern times that antitoxin contains carbolic acid, trikesol or other antiseptic, and that water solutions of these antiseptics of the same strength as that used in preparing the serum, will produce the same effects in diphtheria that the carbolic acid injections have been tested in several thousand hospital cases as well as in private practice and the results are identical with those obtained from antitoxin in the same type of cases I should like to hear what some of your readers think of the above

I am, Sirs, yours faithfully,
Harlesden
August 11th 1902

WHY NOT CLARET?

In The Lancet of July 19th page 193 we referred to the gift of claret which the shippers of Bordeaux wines had offered to the King through King Edward s Hospital Fund for the use of patients in the London hospitals We understand that the amount of wine really offered was 1000 dozen bottles and not 1000 bottles as we stated Moreover the refusal of the gift came directly from King Edward s Hospital Fund Committee and not from Lord Pembroke We can only repeat our regret that the kind offer of the Bordeaux shippers was not accepted

◆

Surgeon—Sometimes the fee is given to the substitute sometimes it is not and sometimes it is divided between the substitute and the patient s usual medical man There is no definite rule in the matter and the last is probably the course to be preferred It is well in such cases for the two medical men to refer the question to a third fellow practitioner as arbitrator unless the matter can be brought to the attention of the ethical committee of any local medical society

Doc Med—An exceptionally good man is independent of degrees and diplomas It is always well, however to obtain the best that are within the student s reach The questions cannot be answered more definitely

Communications not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received—*Literary Digest (New York), Hong Kong Daily Press La Caducée Rivista Medica de San Paulo Il Policlinico Bristol Mercury Birmingham Daily Mail Liverpool Daily Post, Reading Mercury, Southampton Echo Belfast News Dublin Evening Telegraph, Coventry Herald Scientific American Local Government Chronicle Manchester Guardian Hertfordshire Mercury Aberdeen Free Press Echo Times of India Hong Kong Weekly Press Windsor and Eton Express Pharmaceutical Journal, Allgemeine Medicinische Central Zeitung, Sunday Magazine St James s Gazette Kensington News, Ibero-Americana de Ciencias Medicas &c.*

SATURDAY (23rd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing-cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY (18th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—3.30 P.M.: Dr. Saunders: Demonstration in Medical Wards.

TUESDAY (19th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—5 P.M.: Mr. Bidwell: Application of Plaster-of-Paris Splints.

WEDNESDAY (20th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—5 P.M.: Lecture:—Dr. Russell: Aphasia.

THURSDAY (21st).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W.).—4.30 P.M.: Mr. Paget: Demonstration in Surgical Wards.

FRIDAY (22nd).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W.).—4.30 P.M.: Lecture:—Dr. Abraham: Skin Cases.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

THE INDEX TO THE LANCET.

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready. Bound in cloth, gilt lettered, price 18s., carriage extra.

Cases for binding the half year's numbers are now ready. Cloth, gilt lettered, price 2s., by post 2s. 3d.

To be obtained on application to the Manager, accompanied by remittance.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

The rates of subscriptions, post free, either from THE LANCET Offices or from Agents, are:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 12 6	One Year	£1 14 8
Six Months...	0 16 3	Six Months...	0 17 4
Three Months	0 8 2	Three Months	0 8 8

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London and Westminster Bank, Westminster Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE. It has come to the knowledge of the Manager that in some cases higher rates are being charged, on the plea that the heavy weight of THE LANCET necessitates additional postage above the ordinary rate allowed for in the terms of subscriptions. Any demand for increased rates, on this or on any other ground, should be resisted. The Proprietors of THE LANCET have for many years paid, and continue to pay, the whole of the heavy cost of postage on overweight foreign issues, and Agents are authorised to collect, and do so collect, from the Proprietors the cost of such extra postage.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied. Address—THE MANAGER, THE LANCET OFFICES, 423, STRAND, LONDON, ENGLAND.

A Clinical Lecture

ON

THREE CASES OF BANTI'S DISEASE.

Delivered at the Liverpool Royal Infirmary

BY JAMES BARR, M.D. GLASG., F.R.C.P. LOND.,
PHYSICIAN TO THE INFIRMARY AND LECTURER ON CLINICAL MEDICINE, UNIVERSITY COLLEGE, LIVERPOOL.

GENTLEMEN,—I am able to show you to-day three cases of a comparatively rare disease, and as these cases have been for a considerable time under treatment the majority of you must have had frequent opportunities of observing them. These three cases may be legitimately designated as cases of Banti's disease which is usually looked upon as a form of splenic anæmia which is not a very definite nosological or pathological entity. Very interesting papers, with a full bibliography on Banti's disease, by Dr. W. Murrell appeared in the *Medical Press and Circular* of Jan. 8th, 1902, and in THE LANCET of April 26th, 1902, from which we gather that there are not more than from 30 to 40 published cases of splenic anæmia. The pathology of splenic anæmia is not at all settled and there are certainly a great many varieties of disease at present classified under this generic head. As stated by Dr. Murrell, most writers on this subject use the terms "Banti's disease," "splenic anæmia," "splenic cachexia," "splenic pseudo-leukæmia," "lymphadenoma splenica," and "spleno-megalia primitiva" as synonymous. In my opinion many varieties of disease have been more or less closely grouped under these various designations, the conditions common to all being a large spleen with more or less well marked anæmia. Professor Banti[1] of Florence described three cases of progressive anæmia. Clinically he recognised the progress of events as anæmia with enlargement of the spleen and secondary cirrhosis of the liver with ascites. There are frequent hæmorrhages such as epistaxis bleeding of the gums, hæmatemesis, and melæna. Pathologically he recognised fundamental and striking changes in the sympathetic nervous system. In his three cases there were found important changes, not only in the semilunar ganglia and solar plexus of the abdomen, but also in the ganglia of the neck. The changes consisted in lymphoid infiltration of the stroma of the ganglia, fatty and pigment degeneration of the ganglion cells and a degeneration of the nerve fibres springing from the ganglia. In one case there was atrophy of the pancreas with hyperæmic spots in the parenchyma. The lymphoid changes in the bone marrow appeared to him to be such as are usually found as a secondary sequence of anæmia. The changes in the chyle and hæmopoietic organs (as the stomach, the bowels, the spleen and the liver) had a great influence on nutrition, so that the cause of the anæmia in these cases became very apparent. He also mentioned that he had found analogous changes in other constitutional diseases—such as nephritis, diabetes, and Addison's disease. He looked upon the tumefaction or engorgement of the spleen and liver as the primary condition and the fibrosis of these organs which followed as a secondary consequence. Senator[2] considered Banti's disease as splenic anæmia with cirrhosis of the liver and he pointed out the great liability to hæmorrhages in such cases.

I shall now give you a brief abstract of the three cases which I exhibit to you to-day and we will then see how far these cases fit in with the description which has been given of Banti's disease. Some may say that the cases are not complete without post-mortem examinations but the patients and myself hope that such an event may be long deferred. The physical and pathological conditions of the patients are, however, so apparent that there can be no difficulty in arriving at an accurate conclusion as to the morbid anatomy of their viscera. It is true that we cannot tell what changes, if any, have taken place in the sympathetic nervous system, but the state of the circulation points to a paretic condition of the whole splanchnic area in each of the three cases, and I look upon this as an important determining factor in the causation of the disease.

CASE 1.—The patient, a carter, aged 48 years, was first admitted on August 12th, 1901, in a very precarious condition. He stated that he had always enjoyed good health up to four years previously when he met with an accident which injured his abdomen. After this he noticed some swelling but it did not incapacitate him from work. In June, 1901, he strained himself lifting heavy weights and after that the swelling of the abdomen became more marked and about the end of July he had to give up work. For 20 years he drank rum and other spirits but he did not acknowledge to any great excess. He had epistaxis and hæmatemesis on several occasions. On admission he presented the appearance of a man who was suffering from cirrhosis. His dark, sallow, somewhat icteric appearance, injected malar capillaries, shrivelled skin, attenuated extremities, and emaciated frame with large abdomen, all pointed to portal obstruction. His spleen was enormously enlarged, filling the greater part of the left half of the abdomen. The liver was large, firm, and irregular on the surface, and the abdominal cavity was distended with fluid; on two occasions 80 and 134 ounces of clear ascitic fluid were drawn off. There were mitral and tricuspid systolic murmurs with pulsation in the liver and veins of the neck. Friction fremitus was felt all over the abdomen and the fluid did not reaccumulate. He was kept on a dry diet and given salol and digitalis. His spleen diminished much in size, his general state greatly improved and he was discharged in fair condition on Oct. 16th, 1901.

He was readmitted on March 24th, 1902, in a very weak condition, suffering from dyspnœa, cough, and profuse expectoration of frothy mucus. The skin was of a dirty sallow yellow colour and was loose and shrivelled, the conjunctiva had an icteric tinge, there was no subcutaneous fat, the abdomen was much enlarged, and both legs were œdematous. The left pleura was full of fluid and soon afterwards 88 ounces of serous fluid were withdrawn. The heart's action was feeble and the mitral and tricuspid valves were incompetent. The blood pressure was low. An examination of the blood by my house physician, Dr. J. C. Mann, showed hæmoglobin, 40 per cent.; red cells, 2,400,000 per cubic millimetre, and white cells, 5000 per cubic millimetre. The circumference of the abdomen was 41 inches, the abdominal veins were much distended, the liver was large and irregular on its surface, and the spleen was enormously enlarged, extending nearly down to Poupart's ligament and about three inches to the right of the mesial line; the surface was smooth and two large notches about four inches apart could be readily felt. You can feel the same condition in the present day though the spleen is somewhat smaller. He was put first on a terebene mixture and afterwards on one of perchloride of iron and chloride of calcium. On April 11th Dr. Mann's examination of the blood gave the following result: hæmoglobin, 65 per cent.; red cells, 2,560,000 per cubic millimetre; and white cells 8000 per cubic millimetre. A differential count of the white cells gave the following result: large hyaline, 44 per cent.; lymphocytes, 20 per cent.; finely granular oxyphiles 35 per cent.; and eosinophiles 1 per cent. The red cells were normal in shape and size. During the patient's previous residence in the infirmary his temperature was subnormal throughout, but on this occasion there has frequently been an evening rise to 100° F.; in the morning it is usually subnormal. He has recently gained a little flesh and now weighs nine stones and six and three-quarter pounds. He has steadily improved in general condition, and is now able to get about. His chest is quite clear, the heart's action is stronger and he looks much better. His spleen is somewhat smaller but it is still very large; it measures 16½ inches by 13 inches and, I should say, weighs over eight pounds. His liver is still rather large but it does not pulsate. Dr. R. E. Kelly, my present house physician, has recently made an examination of the patient's blood with the following result: erythrocytes, 5,000,000 per cubic millimetre; leucocytes, 12,600 per cubic millimetre; hæmoglobin, 60 per cent.; hæmoglobin value of each corpuscle, 60 per cent. His cardiac area is small, the deep dulness extending one and a quarter inches to the right and three and three-quarter inches to the left of the mesial line. At the apex the first sound is dull and murmurish, the second is clear but not accentuated. At the aortic area there are a systolic murmur and a clear second sound. At the tricuspid area the first sound is followed by a short systolic murmur and a clear second sound There is systolic pulsation in the veins of the neck. The blood pressure is low, with Hill and Barnard's sphygmometer the pressure in the brachial artery is, in the recumbent posture, mean 100 millimetres of mercury, obliterating pressure 150 millimetres of mercury In the sitting posture mean is 110, and the obliterating 160, millimetres of mercury In the illustration (Fig 1) the outline of the patient's spleen is traced

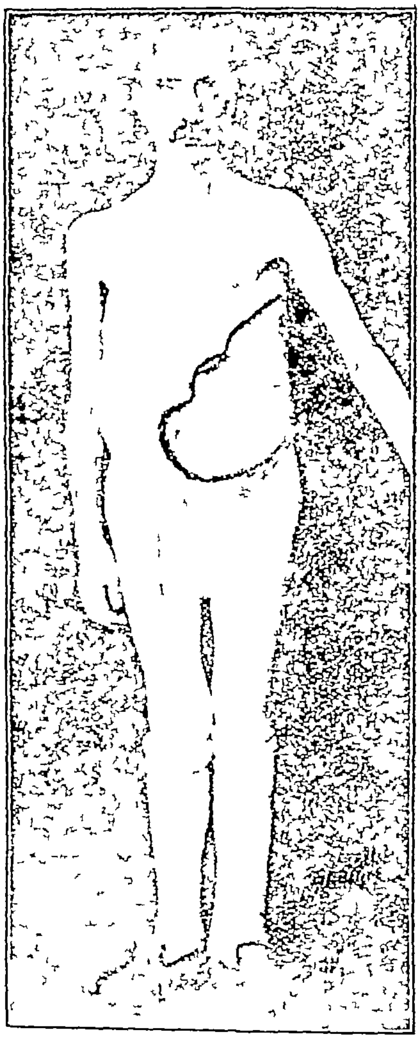
FIG 1.



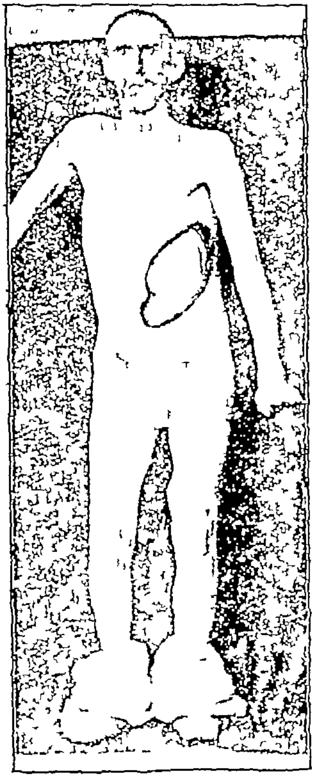
From a photograph of the patient in Case 1 The outline shows the size of the spleen

CASE 2.—The patient, a male, aged 42 years, has been a cotton porter for the last five years, and a coal miner previously to that, which was evidenced by the whole of his skin being studded with particles of embedded coal dust. He was admitted to Mr F T Paul's ward on Nov 2nd, 1901, on account of Morton s disease, but Mr Paul did not think him a fit subject for operation and he was transferred to my male ward on Nov 16th It was then evident that metatarsalgia was only a minor part of his ailment. About 20 years ago he met with an accident to his spine in a coalpit, and the spines of the lumbar vertebræ are now very prominent Five years ago he vomited blood, and again in May, 1901, he had such a severe attack of hæmatemesis that he was unconscious for a couple of days He thought that he vomited about two quarts In Mr Paul's ward he had another attack of hæmatemesis, this and his appearance led at once to the investigation of his liver for cirrhosis, though he said that he never drank more than a pint of beer daily He presented a distinctly sallow, icteric tinge with large malar capillaries, loose shrivelled skin, considerable emaciation with absence of subcutaneous fat, large abdomen, but no ascites His lips were dry, his teeth were good and were covered with sordes, his tongue was dry brown, and tremulous, and the anterior half was rather denuded of epithelium, his gums were soft and spongy and bled readily, and he suffered from thirst, his stomach was not enlarged and he had no pain after food His liver was large and irregular on the surface. His spleen was large and the notch was easily felt The area of the heart was increased, to the right there was a tricuspid systolic murmur The blood count gave hæmoglobin 30 per cent. and red corpuscles 5,000,000 per cubic millimetre, the white cells were not counted but there were about an equal number of mononuclear and multinuclear cells. The lungs were normal. The urine amounted to 41 ounces, it was highly coloured and had a specific gravity of 1014, a slight trace of albumin and bile was present, urea, 2 5 per cent. There was considerable pain at the distal end of the fourth metatarsal phalanx of the right foot, the knee jerks were present but were not well marked There was slight swelling of both feet and in the right knee joint The pain in the right foot was so severe as to keep him awake at night Dr Mann examined the blood on April 12th and found hæmoglobin 56 per cent and red cells 6,000,000, and white cells 12,000, per cubic millimetre. Again, on April 13th the blood count gave hæmoglobin, 65 per cent., red cells, 6,500 000 per cubic millimetre, and white cells, 16,000 per cubic millimetre

The progress in this case has been very slow and the patient has had a great variety of symptomatic treatment which I will try to summarise The pains in the feet have given rise to a great amount of trouble Very soon both feet became involved, and they were so exquisitely tender that he could scarcely bear to have them touched, they were much swollen, red, hot, and tender and he could not bear to have them depressed The pain was equally severe in both feet and was not confined to any particular spots, though the greatest pain was caused by lateral pressure on the distal ends of the metatarsal bones It was evident that we had a severe case of erythromelalgia of both feet. For this pain morphia and Dover s powder were administered internally and various liniments externally He had electric foot baths and his feet were immersed for hours daily in very hot water which seemed to do good, but what has really enabled him to get on his feet has been wrapping them in cottonwool and then applying tightly over this an elastic bandage The good effect of this is very apparent when you now see him walking about in his bandages, whereas a short time ago his feet had to be elevated about 18 inches above the rest of his body in order to afford him some relief For the pain and swelling in his knee and ankle joints iodide of potassium and salicylate of sodium were given His spongy gums, raw tongue, and pharyngitis gave some trouble but were relieved by the local application of nitrate of silver and the internal administration of lime juice and cream of tartar As general tonics he has had strychnine, digitalis, quinine, and hydrochloric acid Since April 12th he has been taking with advantage a mixture of the perchloride of iron and chloride of calcium. His diet throughout has been light and nutritious and rather dry He is now much better and is able to get about His digestive organs are in a fair condition, his liver and spleen are much smaller, though both are still much larger than normal The spleen measures 10 by five and a half inches There has been no ascites, his urine is now normal His heart is fairly normal and is now without any tricuspid regurgitation, there is still pain in his feet and I am afraid without the bandages he would not be able to get about His temperature has been subnormal throughout. The peculiar condition of his blood, showing an excess of both red and white cells, may be partly due to his dry diet and the limited amount of fluid in his tissues At present the area of the heart is rather small, the deep percussion extending one and a half inches to the right and four inches to the left of the mesial line The sounds are sharp and clear and free from murmur The blood pressure in the brachial artery with Hill and Barnard's sphygmometer is, in the recumbent posture, mean, 96 millimetres of mercury, and the obliterating pressure is 136 millimetres of mercury, in the sitting posture it is mean 100, and obliterating pressure 146, millimetres of mercury Dr Kelly's examination of the blood gives the following result: erythrocytes 7,000,000 per cubic millimetre, leucocytes, 13,000 per cubic millimetre, hæmoglobin, 70 per cent, hæmoglobin value of each corpuscle, 50 per cent. The patient's gums are still very spongy and his tongue is red and raw His lips and finger ends are of good colour The tip of one of his toes is gangrenous, not an uncommon event in erythromelalgia. A reproduction of his photograph is appended. (Fig 2.)

CASE 3.—A man aged 38 years, was admitted under the care of Mr Paul on June 14th 1901, for a large tumour in the left hypochondrium. Mr Paul explored and found a large vascular spleen which bled profusely on the slightest handling. The liver was found to be rather large *and smooth* but otherwise it was normal. The wound was closed and when it had healed the man was transferred to my ward on July 12th. About five years ago when jumping a hurdle he caught his toes and fell violently forwards hurting his chest and abdomen. He was then in bed for two weeks. After this he continued fit for work but during the last six months he had lost a stone in weight. About seven or eight weeks ago he first noticed severe pain in the cardiac area shooting across from nipple to nipple. After food this pain became localised in the epigastrium. There was no vomiting and his bowels were very constipated, there being five or six days between the movements lately there was melæna. His condition when in my ward may be summarised as follows. On admission he was so extremely prostrate and his blood pressure was so low that even propping him up in bed made him feel faint. He was much emaciated and rather anæmic his skin was loose and dry with no subcutaneous fat, he had a slight icteric tinge of the conjunctivæ the mucous membrane of the mouth was of a dark red colour and the tongue was red and denuded of epithelium. The area of the heart was small the sounds were short and clear the first sound being accompanied by a systolic murmur at the apex. Dr Mann's examination of the blood showed 2,800 000 red cells and no excess of leucocytes. The lungs were normal. The abdomen was much distended. The spleen was very much enlarged filling the left hypochondrium, lumbar and left half of the umbilical regions. Hepatic dulness measured three and a half inches in the nipple line, and the lower border which was sharp and smooth, could be felt below the costal margin. The urine was normal. He was put on a light diet, had a mouth wash of carbolic acid and formaldehyde salol internally and occasionally a dose of calomel. About a fortnight after admission his spleen began to shrink but his abdomen filled with fluid. Between that time and the end of October he was tapped nine times, the average amount drawn off being 264 ounces. On August 10th 44 ounces of sanious fluid were drawn off from his left pleura, but a second operation was not required. Friction was heard and felt and eventually the pleural surface became adherent.

FIG 2.



From a photograph of the patient in Case 2. The outline shows the size of the spleen.

It was necessary to settle the question of tuberculous peritonitis and accordingly some of the ascitic fluid was injected into a guinea pig at the Thompson Yates laboratories but with a negative result. By the end of October he had improved very much in general condition and the spleen had shrunken so that it could only be felt below the costal margin. I thought it useless to continue the tapping so I sent him back to Mr Paul with the view of having his abdomen drained. Mr Paul operated on Nov 4th and left the drainage-tubes in for about 10 days, but when they were removed the wound healed and the fluid reaccumulated. He operated again on Jan. 2nd 1902, and drained until the 17th. At each of these operations it was noticed that the parietal peritoneum was extremely vascular but the visceral layer was an opaque white, very like the condition of leucoplakia. After the last operation numerous adhesions took place and the right half of the peritoneal cavity was practically obliterated. On March 6th there was a large loculated collection of pus in the left hypochondrium and lumbar regions. Mr Bickersteth operated for Mr Paul this abscess was thoroughly drained until April 15th. The wounds have healed for some time and he has now returned from the convalescent home.

The following note was made on May 22nd 'Great improvement has taken place in the condition of this patient. He can now get about and attend to his business. He enjoys his food but occasionally after meals he feels uncomfortable and distended with flatus. His legs occasionally swell in the evening. The right radial artery with Oliver's arteriometer measures in the recumbent posture 3 3 millimetres in the erect posture it measures 2 8 millimetres with Hill and Barnard's sphygmometer the blood pressure in the brachial artery in the recumbent posture is mean 103 millimetres obliterating 156 millimetres in the erect posture it is mean 98 millimetres obliterating 152 millimetres of mercury. The cardiac area extends two inches to the right and four and a half inches to the left of the mesial line. The apex beat is situated in the fifth interspace gently heaving. The first sound is dull at the apex followed by a short second sound. At the tricuspid area the first sound is dull but no murmurs are present. At the base the second sound is double the final element being pulmonic. The veins of the neck are somewhat distended when he is lying down and show slight systolic pulsation they empty with inspiration. There are a few harsh sonorous râles over the chest. The expansion of the left side is not quite so good as on the right side and the left intercostals are drawn in during inspiration the percussion note throughout is good. At the base of the left lung the vesicular murmur is rather [illegible] and defective [illegible] and measures fo [illegible] pira five and a ha [illegible] tion the edge of the liver feels smooth and rounded. The spleen fills the greater part of the left hypochondrium and forms an irregular oval measuring eight inches by six inches the lower margin which extends about two inches below the border of the ribs is felt to be hard and firm with smooth surface. The rest of the abdomen is tympanitic but a diffuse thickening is felt all over evidently due to peritoneal adhesions. There are four scars at the site of the old operation wounds. The circumference at the level of the umbilicus is 35 inches. The tongue is clean, the mucous membrane is rather purplish and congested, the gums are spongy the malar capillaries are rather large and the ears are congested and feel cold. The blood-count was as follows: hæmoglobin, 85 per cent.; red corpuscles, 5,120,000 per cubic millimetre; white, 11,560 per cubic millimetre; polynuclear cells, 72; lymphocytes, 18; eosinophile, 7; and hyaline, 3 per cent. The temperature in this case was subnormal except on a few occasions, when it reached 99·2°; there was usually a range of one to two degrees between the morning and evening temperatures."

This man on admission was decidedly anæmic and Dr. Mann on one occasion found that his red corpuscles only numbered 2,800,000 per cubic millimetre with no excess of leucocytes, but examinations of his blood were not made regularly, as during the early period of his residence in hospital, before I had had an opportunity of seeing his peritoneum, I looked upon the case as one of chronic tuberculous peritonitis with an enlarged spleen. The occurrence of sanious fluid in the pleural cavity supported that view as cases of polyomenorrhitis are nearly always tuberculous. After an examination of the peritoneal cavity and its contents and watching the progress of the case that view was set aside and I have placed the case with the other two as one of Banti's disease. If this view be correct the present condition of the patient shows that Banti's disease is not necessarily fatal but even capable of being practically cured.

We can now compare these three cases. They are all males, aged respectively 48, 42, and 38 years. Each one met with a more or less serious accident to his abdomen some years before the occurrence of the present disease. There is nothing in the family history of any of them which could have any bearing on the disease. They have never been out of this country. There is no history of syphilis in any case; the first man may have taken more alcohol than was good for him, but there is no such history in either of the other two cases. The blood pressure was low in all the cases, this no doubt being due to vaso-motor paresis of the splanchnic area, and it was so very low in the third case that for a long time the foot of his bed had to be raised in order to maintain his cerebral circulation. This lessened peripheral resistance in each case led to more or less cardiac atrophy and in no case is the heart of such size and power as would be required by a labouring man. The abdominal viscera in each case have been engorged while the vessels of the rest of the body have been comparatively empty. The skin has been loose and shrivelled, there has been almost complete disappearance of the subcutaneous fat, and the muscles have been atrophied. In none of the cases was there such partial obstruction as would account for these latter phenomena. In all the cases there has been a low form of chronic peritonitis with marked friction fremitus, but without any febrile temperature. In Case 1 and Case 3 there were ascitic and pleural effusions, but the complete disappearance of the fluid in the first case after a couple of tappings showed that the ascites was not due to the cirrhosis, and in the latter case at the operations the liver was found to be fairly normal. In Case 2 the albuminuria indicated renal engorgement and the well marked erythromelalgia of both feet showed further vaso-motor paresis. The three spleens are now very firm and no doubt undergoing fibroid changes. In Case 3 the great enlargement at first was simply due to engorgement, as evidenced by the great shrinkage which has taken place. The spleen is normally a very spongy organ and capable of great variations in size. It is also, as Dr. William Hunter has well shown, a blood-destroying organ, and during the early stage of engorgement this function would be increased and the excessive hæmolysis would lead to the anæmia which is such a distinctive feature of the disease. When the fibrosis is well established the hæmolysis would diminish and might reasonably be supposed even to sink below normal; that such has here happened is shown by the increase of erythrocytes in Case 2 to 7,000,000, in Case 1 to 5,000,000, and in Case 3 to 5,120,000 per cubic millimetre.

In all these cases there was marked oligochromæmia. In the early stages there were considerable diminution of the erythrocytes without any alteration in their size or shape and no excessive leucocytosis. The great diminution in the red cells referred to by Dr. Murrell would seem to be no necessary part of the disease but would rather tend to show that such cases should be grouped with those of pernicious anæmia. If my view of this disease be correct then it is highly probable that the primary reduction may eventually end in an excessive number of erythrocytes if the patients live long enough.

In my male ward you will at present find an extreme case of pernicious anæmia where the red cells number less than 500,000 in the cubic millimetre. In these cases, especially in Case 2 and Case 3, there has been a pronounced hæmorrhagic tendency. In Case 1 and Case 2 there is distinct cirrhosis of the liver without any marked portal obstruction. If there be yet any cirrhosis in Case 3 it must be slight.

I now show you a patient suffering from alcoholic hepatic cirrhosis who has been tapped many times in order that you may compare him with the other three patients. In his case there is no marked enlargement of the spleen, and although in such cases there is usually cardiac asthenia with incompetence of the tricuspid valve, yet there is no such fall in the peripheral blood pressure as that which occurred in the cases which I have been describing. I had also recently in my ward a well marked case of leucocythæmia who has greatly improved and is now an out-patient. You will find his spleen very large, firm, and smooth, but an examination of his blood at once places the case in a different category.

In Case 2 the slight icteric tinge and absence of ascites may raise the question of biliary or hypertrophic cirrhosis of Hanot, but in that disease the jaundice is much more pronounced, there is more or less febrile disturbance, and marked leucocytosis; the liver and spleen are both enlarged but the liver is smooth on the surface and the cirrhosis is monolobular. In this case the spleen is greatly enlarged, the liver is large and hob nailed on the surface, so the cirrhosis is of the multilobular variety. There have been no fever, no leucocytosis, and no marked jaundice.

In conclusion, I may say that my view of Banti's disease is that it is probably due to a vaso-motor paresis of the splanchnic area, either in whole or in part, and that this paresis arises from disease of the visceral sympathetic ganglia. As a consequence there is great engorgement of the abdominal viscera, especially of the spleen and liver, increased hæmolysis with consequent oligochromæmia and oligocythæmia. The increased blood supply to those organs eventually leads to fibrosis and lessened function. The peritoneal effusion when it takes place would seem to be due to vascularity rather than portal obstruction. The paresis leads to retention of blood in the portal area with lessened supply to the rest of the body, fall in the general blood pressure with lessened work for the heart, impairment of nutrition, and muscular atrophy. The digestion is usually impaired, there is apt to be an increase of toxins in the intestinal tract, with further aggravation of the mischief. The engorgement of the viscera and mucous membrane generally is a frequent source of hæmorrhage.

Splenectomy has been recommended and, I may add, practised as the best method of treatment for this disease. It may be an excellent treatment for the disease, but in every case you have got to consider the patient rather than the disease. In Case 1 and Case 3 such a procedure would certainly have proved fatal and in Case 2 the spleen at present is not sufficiently active and therefore I cannot see the *raison d'etre* for its removal. I do not think in his case that it would be fatal, but it might set up in time leukæmia which would be as difficult to treat as his present illness. We may try something to assist the spleen and to increase the hæmolysis. We must get beyond the spleen, we must try to reach the nerves and ganglia which supply the spleen and other viscera. We must as far as possible raise the general blood pressure, improve the nutrition, and keep the intestinal tract as antiseptic as possible. For the latter purpose I prescribe salol, benzo-naphthol, and an occasional saline purge; for the former such drugs as strychnine, digitalis, quinine, and caffeine are useful. I am fond of the perchloride of iron with chloride of calcium as a good hæmatinic and vascular tonic, and it also lessens the liability to hæmorrhage. I have not tried arsenic systematically in these cases, as on *a priori* grounds I did not expect any benefit from its use. In the first two cases I am at present trying suprarenal capsules. Of course, in the early stage the patient should be kept in bed. It is probable that a large elastic abdominal belt firmly applied would do good.

The diet should be light, plain, simple, and easily digested, such as peptonised bread and milk, raw eggs, milk puddings, bread and butter, fish, chicken, mutton broth, ripe fruit, tea, coffee, and milk. As there is not so much obstruction to the portal circulation in the liver as in an ordinary case of cirrhosis there is not the same necessity for limiting the quantity of fluid drunk. The following jelly I find an agreeable method of introducing chloride of calcium into the system. Take about an ounce of gelatin, the juice of one lemon, from two to four drachms of chloride of calcium, and one pint of hot water Dissolve the gelatin, &c. allow to set, and it is then ready for use.

For the ascites Dr Murrell recommended the operation of epiplopexy In Case 3 drainage as carried out by Mr Paul answered admirably and I think in the majority of such cases is likely to do better than epiplopexy In these cases there is not very great obstruction to the portal circulation and so no great necessity for establishing a collateral circulation. You want rather to abolish or to limit the secreting surface. I think that cases curable by epiplopexy can be cured by simpler means. The treatment in these three cases has been to a certain extent successful and I hope by attention to minute details that further improvements will take place.

Note (*August 12th*).—Cases 1 and 3, when last seen, were in very fair condition Case 2 is still in the infirmary suffering from gangrene of several toes in connexion with his erythromelalgia.

An Address

ON

HEART DISEASE IN CHILDREN

Delivered at the Manchester Children's Hospital, Pendlebury before the Society for the Study of Disease in Children,

BY A. E SANSOM, M D, F R C P LOND,

CONSULTING PHYSICIAN TO THE LONDON HOSPITAL.

MR. CHAIRMAN AND GENTLEMEN —In the first place I have not a paper to read I have only a few remarks to make. Some of us are pretty well accustomed to a few remarks" and they may be agreeable or they may be otherwise But I have a very agreeable task in the first place and that is to thank the authorities of this Pendlebury Hospital especially our chairman (Dr H Ashby) on this occasion, whom all revere and for whom we have a very great affection, for their goodness in allowing us to come here and to see the wealth of material which they have. It is all very well to make apologies for the wards but it seems to me there is no place in the whole country—or I think I may say in any other country—in which disease in children is better to be observed and is better observed and studied than here And let me say on the part of the members of our society that it is not only honoured but it honours the place. The society is founded upon the best principles I believe and I think the title is one that is worthy of all commendation There is no glamour about it it is a Society for the *Study* of Disease in Children" and it is upon those lines that I have to make a very few remarks before the meeting upon heart disease in children.

When we look over the great realm of children's diseases and when we narrow our view to the question of organic heart affections in children I should say that in the enormous proportion it is the *rheumatic* heart which we have to deal with. It is quite true to say that, in children especially we have to consider anomalies and malformations. But even when we do consider malformations of the heart, which we do not hear of so much in adults because unfortunately life is not preserved long enough we find in a very large number of cases—and especially do those find it who like Dr Theodore Fisher study it in the post mortem room—that there is not infrequently *superadded to it a form of disease* essentially of a rheumatic nature that is, so far as we have morbid anatomy to guide us. And that is no original observation It was made by Dr T B. Peacock in the very early periods of investigation on the subject So that even when we have malformations to consider we have the superaddition of rheumatic troubles to think of also. And then in any case in children where the question of congenital anomaly comes in, we have to think whether that seemingly congenital anomaly is due to intra uterine endocarditis or whether it is due to congenital malformation Now there is such a thing as congenital endocarditis That I have proved myself and I know many others have clearly proved it also It becomes us, therefore, to question in any case of seeming congenital anomaly whether there is not also a question of congenital endocarditis in the case.

In this communication I propose to consider only the following groups of what I will call the chief condition of heart disease in children, the rheumatic heart of childhood The congenital anomalies I shall not consider at all, they are too rare for my present subject I shall only consider the more common forms of heart disease in children Those more common forms I would classify as examples of the *rheumatic heart* Now the groups varieties, and phases of the rheumatic heart which I propose to consider are, (1) the temporarily swollen or enlarged heart of rheumatism, (2) the heart of rheumatic pericarditis, (3) the heart of rheumatic endocarditis with resulting valvular disease, severe or extensive and (4) the heart of slow insidious *endocarditis inducing mitral stenosis* By '*rheumatic*" I mean a morbid condition in strict relation with my conception of the rheumatic process, the phenomena of true rheumatism I do not consider any specially painful implication of the joints to be necessarily an index of this condition It may be strange to say that rheumatism is not essentially a painful disease but that is my *deliberate conviction The arthritis of true rheumatism is* certainly very painful in some cases—painful while it lasts; but it is singularly controlled and influenced for good by medicines such as salicin and the salicylates, and very rarely lasts more than a fortnight. At the end of that time the pains and swellings of the joints disappear leaving no permanent morbid changes, though there may be and often are, waves or storms of recurrence There are many cases of arthritis which are not rheumatic I am of opinion that osteo-arthritis so-called rheumatic gout is dependent in many cases upon infections which have no relation with rheumatism, that the morbid changes in this disease are more permanent the pains are much more severe and protracted and the resulting deformities are more significant than in the case of true rheumatism.

Now here I must just call your attention to somewhat of a rarity *that is to say osteo-arthritis in children* and the lessons which I think it teaches us. It may be remembered—and you will see it in the published volume of the reports of this society—that I brought forward a case of osteo-arthritis in a child It was in a boy aged 11 years. The disease does not occur generally at a very early age The joints in that case were swollen nearly all the large joints were involved and it was very long lasting—six months under our own observation There was a little improvement under massage, and so on but not very much. It did not comport itself in the way that I think is usual in acute rheumatism generally Acute rheumatism in the child is evidenced mostly by rise of temperature by painfulness which may be very slightly marked in a few joints, by anæmia by skin troubles of certain forms (especially erythema) by peliosis rheumatica" *as it is called (purpura)* and *sometimes* by urticaria. *It is very doubtful whether other forms* of erythema like erythema nodosum are associated with rheumatism. I do not think that erythema nodosum has anything to do with rheumatism but at any rate rheumatism is attended by some skin affections and by rises of temperature. But in childhood as I need not say to members of this society who have plenty of opportunities for investigation we find that the heart phenomena—not complications—of rheumatism are very much to the fore that there may be pericarditis, there may be endocarditis and there may be the swollen heart of rheumatism without any signs to show that there are arthritic phenomena present They exemplify a form of rheumatism a very marked phase of the rheumatic process in the child without the intervention of arthritis to interpret it as rheumatic Therefore it does not do for us to take arthritis as an index of rheumatism

There are other things which come before us so markedly in child's rheumatism To come back to this case which I spoke of and its lessons there were very marked painfulnesses lasting at least for six months and very marked deformities. Twelve months later I had the opportunity of seeing the child again for he has been under my care for a considerable time The characteristic lessons I think, are these that the arthriticism, the arthritic conditions are much less but the wasting conditions are very marked indeed So marked is the wasting of muscles and the deformities which result from the wasting of muscles that I have been able to base some remarks to my clinical clerks and house physicians upon them and to say in some cases—I say it now with plenty of opportunity of correction because I know very well that you will correct me if you think I am not right—that some cases of this form of arthritis are non rheumatic, and that in some the arthritis is in excess of the neuritis and in others the neuritis is in excess of the arthritis This boy has no cardiac lesion nor any approach to one The form of arthritis of which I speak is not rheumatic, according to the best of my knowledge and belief. Sometimes the arthritis is more pronounced than the nerve phenomena, sometimes the nerve phenomena are more severe than the joint phenomena, and it is a question very often of the preponderance of the one or the other In the so-called "rheumatic gout" of children there may be very much destruction and alteration of joints or there may be very little alteration of joints, and yet there may be a great deal of wasting owing to nerve causes I have had some photographs and radiographs taken of this case and they will compare with those which are in the former volume of our Transactions I think the radiographs show that the chief signs are in the feet and that the swellings which were about the joints, as shown by the radiographs, are very much less, whereas the deformity and wasting are still very marked indeed, although less in the hands than formerly

To come, then, to our former topic, the rheumatic heart of childhood, this is essentially a rheumatic phenomenon, and it very often is not to be interpreted by any form of arthritis at all The heart of osteo-arthritis is a very irritable heart, sometimes inclined to quicken, sometimes inclined to be slow, and sometimes to be irregular But it is not associated with any organic disease of rheumatic type

And now you may say that I have been labouring rather to show that the common notion of taking arthritis and painful joints as signs of rheumatism is not a justifiable thing and that we who study disease in children are essentially disposed to combat that usual notion so prevalent amongst the public—and I may say those members of our own profession whose practice does not lie so very much amongst children Rheumatism is not essentially a joint process, it is only adventitiously a joint process

I will now briefly refer to the first group which I have mentioned, of the truly rheumatic heart in children, and I will say that, so far as my own experience goes, it entirely endorses the observations of my friends Dr D B Lees and Dr F J Poynton who have shown that in child rheumatism as well as in the rheumatic fever of adults the heart may be temporarily enlarged I have frequently found that to be the case in the wards and I have demonstrated it I do not think you want any very severe or unusual processes to demonstrate that—your own fingers are the best thing The first point is to find out where the pulsations of the heart are to be felt If they are to be felt outside the normal position, to the left or to the right, you make a note of it. Then I agree with Dr Lees that when you have found the points where the beat is felt (I do not like the term "diffuse beat") —when it is felt at more than one interspace—you can reckon that the ventricle extends at least a finger's breadth outside that, and you may use percussion to determine that enlargement with very great advantage. But when it comes to the question of the mode of percussion I do not think I quite agree with Dr Lees in thinking that the finger of the observer is the very best method I think that it is the best as a percusser but not as a pleximeter, but you must remember that I am a little biased, for I like my little pleximeter best because I think it gives the most accurate results, as did Piorry I was a pupil of Piorry many years ago—he has been dead for some years—and he used to say, and I thought then with a very good show of reason, that the soft cushion of the finger does not give you as good results as something which is rigid and which therefore shows the vibrations better I think that he was right. I agree with Dr Lees in the main and these are only observations, perhaps a little outside the practical If you find by means of the finger the point of extreme pulsation and then apply your finger outside you get very fairly the outline of the enlarged heart—that is to say, one finger s breath away That it is enlarged in rheumatism I entirely agree It may be temporarily enlarged and then in the course of 24 hours it may recover Or it may take several days to recover, in fact, it goes through the phases of an ordinarily enlarged and swollen joint, according to the best of my knowledge and belief That sometimes occurs in pre-existing disease of the heart, and sometimes in a sound heart, and the subjects of that heart have no distressful symptoms or need not have The heart, according to some members of our profession and according to some observers, is dilated Well, I agree that it may be so But why is it dilated? Is it dilated because there is any particular form of myocarditis? I do not think so I am sorry to confess, as this is a society for the study of disease in children, that I know very little, or even nothing, clinically, about myocarditis. We read of myocarditis, but I do not know of any clinical sign by which I could determine that there was myocarditis I do not know even whether in these cases there may be any degeneration as a consequence of such myocarditis I should think not, because the heart resumes its normal size and shape so readily and quickly What do I know about it? The opinion which I recorded many years ago in my 'Lettsomian Lectures" is that the heart is *infiltrated* under such circumstances, and I demonstrated that it is infiltrated Therefore I should say—and I think that Dr Fisher, who has written on this question an exceedingly good paper in THE LANCET,[1] is of my opinion and that Dr Lees and Dr F J Poynton and Dr Payne are also of my opinion—that there is something which enfeebles the heart, but it is not of the nature of the ordinary form of inflammatory trouble or degeneration, it is an infiltration which cripples the heart

If that is so, let us think to what very important points it leads us It is that the dilatation of the heart is not an unusual phenomenon, it is a fairly common phenomenon. If Dr Lees is right—and I think he is—it occurs almost invariably in any form of rheumatic disease of the heart. But the heart enlarges without any particular sign as regards the patient and by and by it gets normal again Well, those observers who hail from Germany tell us that dilatation of the heart is such a fearful thing that it has to be observed by the nurses every hour and tested by the sphygmograph, and the patient s attention must be constantly directed to it But it seems to me that that is very unreasonable, inasmuch as the change is not accompanied by any special signs, and the patient makes a very good recovery in a considerable number of cases, though not in all But even supposing that there is a heart already diseased, the temporary dilatation that accompanies the rheumatic process does not make a great deal of difference unless the disease within the heart increases, and that it very often does, from pericarditis or endocarditis, or both But I do not think we may say that dilatation of the heart, as such, is a thing of the greatest immediate consequence and of the significance which we have been told And I may go further and say that dilatation of the heart, in some cases even of valvular disease, is a very good thing For example, if you find a crippled mitral valve, a regurgitant condition of mitral insufficiency, it is a very good thing to have some dilatation of the left ventricle You would not get compensation unless you had In such a case the left ventricle drives some of the blood back into the left auricle and does not send so much into the aorta, but fails by and by, in the process of time, to send sufficient for the nutritive needs of the organism It must therefore hold more, and to hold more it must be dilated Therefore I do not think that we can agree that dilatation is *always* of the severe and grave significance that some people think. I quite agree that in aortic disease painful conditions occur and that there may be something of distension of a serious kind in that condition, but in the great majority of cases the dilated heart is not of necessity of the significance that some people have made out

So much for polemics I have already said that the heart of rheumatism is a heart that enlarges, and rheumatism in all its forms is a dangerous thing as regards the heart and produces organic disease, but the rheumatic gout or osteo-arthritic form is not productive of any disease of the heart but brings about an over sensitiveness of the nerve mechanism of the heart

The heart of rheumatic pericarditis I have not time to consider now With regard to the heart of rheumatic endocarditis, with increasing valvular disease, we know the extreme significance of that, and the heart of slow and insidious rheumatic endocarditis inducing mitral stenosis This latter I think I should say a few words upon because it has been a subject of very long study with me The disease known as mitral stenosis is a very subtle one—so subtle that, as I have said before, it has been considered to be a form of congenital anomaly It may occur in intra uterine life, it is quite free from symptoms in its origin and progress, and it is generally only when the child is from 7 to 12 years of age that it becomes strongly marked and is detected.

---

[1] THE LANCET, June 7th, 1902 p 1594

The smoothness of the funnel shaped mitral valve has sometimes suggested that it is a congenital anomaly but I believe that it is not so The disease I think, is rheumatic and only rheumatic, because I have seen those cases ultimately in the course of time develop true and undoubted rheumatism, though some observers especially French have *thought, from the insidious character of it that it is not* rheumatic *ab origine* but tuberculous. I think that there is no such likelihood I think that it is rheumatic but very gradual in onset and in progress

I have endeavoured to bring before you what my conception of rheumatism with regard to the heart is. That opinion is not worth much only in so far as you endorse the opinions which I give and submit them to that actual study which is the province of this society But I think we should try to persuade our brethren to alter their conceptions of rheumatism and to remember that rheumatism is a very subtle and gradual form of disease that all arthritis is not rheumatic—in fact that there are many other causes of arthritis in both children and adults than rheumatism that heart affections are peculiarly symptomless very often in origin and progress, that the treatment of them must be conducted on rational lines and that anything in the nature of methods *ad captandum* ought not to be applied to them.

Those are the observations I had to make and I am only exceedingly sorry to have taken up so much time in developing them I am only delighted to have done anything at all.

Clinical Remarks

ON

THE CAUSES WHICH PREVENT THE RESTORATION OF NORMAL VALVE FUNCTION IN RHEUMATIC ENDOCARDITIS.

Delivered at the Liverpool Royal Infirmary

BY RICHARD CATON, M D EDIN,
F R.C P LOND,
HONORARY PHYSICIAN TO THE INFIRMARY

GENTLEMEN —You have seen many examples of acute articular rheumatism and you have observed how severe the lesion in the joints may be, how great the swelling the pain, and the effusion and yet in most cases, if the joint has the needful rest and protection from external chill if a suitable diet be given and gentle cholagogues with salicylates are administered you have observed how speedily all these grave symptoms subside or if in any joint they linger you have witnessed their rapid subsidence on the application of one or two small blisters to the adjacent skin the final issue in almost all cases being the restoration of every joint to the normal condition.

But why is it that when the *heart* is attacked in rheumatism a like restoration of the endocardium does not take place? Why when a bruit at the apex has occurred during acute rheumatism does the regurgitation it indicates with accompanying accentuation of the second pulmonary sound not also disappear when the patient rises from his bed cured of his pain and fever? Why is it that if we leave the rheumatic heart to its own course persistent bruit hypertrophy and dilatation—in fact, life-long heart disease with its train of attendant evils—succeed and are sure to mar or to shorten the life of the patient? Why should the course of rheumatic disease be so much more intractable in the heart than in the joints?

The reason undoubtedly is found in the fact that joints can rest; the merciful influence of pain automatically ensures repose for each affected joint. Suppose for a moment that we were to cause an acutely rheumatic knee to be flexed and extended 80 or 100 times per minute during the whole period of the attack is there any probability that resolution would follow? Few of you, I fancy would expect it. Rheumatic inflammation of the valve cusps usually does not cause any pain but whether there be pain or no the toiling heart cannot abate its labours In fact, the joint pain and the general fever augment and accelerate the ventricular effort, thus increasing the peril of the heart. Though the salicyl compounds have, as most people believe no direct beneficial action on valvulitis I think that they have an indirect one of much importance through their power *of allaying the pain and fever which in themselves excite the* heart's action.

You have observed how commencing endocarditis is treated in my wards and those of you who have been able to watch cases for a sufficiently long time have observed that the results are usually favourable. The principle we go upon is to give the heart the greatest amount of rest that is practicable. Pain and fever are subdued as rapidly as possible, absolute quiet is enjoined the patient lies with the head low no excitement is permitted we make him as comfortable as we can and encourage sleep, and a light non stimulating diet is given. There can I think, be little doubt that slow ventricular contraction, low vascular tension—in fact, a minimum of work—is essential if the inflamed and thickening endocardium is to be restored to its normal condition. We also, as you know employ other measures of less importance (1) gentle blistering of those areas of skin which have a special nerve connexion with the heart, thus imitating the effect of a blister over a rheumatic joint and (2) the administration of moderate doses of sodium iodide. I wish to-day to show you certain cases and to tell you of others which I cannot show illustrating the subject of this lecture.

CASE 1.—A man aged 21 years was admitted into the hospital on April 27th 1900 suffering from acute rheumatism and endocarditis His temperature was 102° F his pulse was 98, and there were a loud systolic apical bruit and accentuation of the second pulmonary sound The rheumatism soon subsided and under appropriate treatment all signs of valvulitis also vanished in little over a month I am sorry to say I now made a mistake. Quite in opposition to my ordinary practice and precept I allowed this man to leave his bed. Within two or three days all the signs of endocardial mischief returned the strain to which the heart was thus exposed at too early a period of convalescence caused a recrudescence of the valvulitis. The patient had to return to bed small blisters and iodides were again resorted to These measures, in addition to absolute rest maintained for seven weeks, were followed by a second disappearance of all the symptoms All hard work was interdicted for two months longer after which he returned to the duties of his calling He has now been hard at work for two years He has no dyspnœa, he can climb stairs and carry heavy weights as well as any man he will tell you that he is as strong as he ever was and if you examine his heart you will find that the dulness is only three and a half inches to the left of the middle line the impulse is normal and so are the sounds.

CASE 2.—This man came into the hospital on Feb 22nd with acute rheumatism his temperature being 103° F and his pulse 120 and within a day or two of his admission signs of endocarditis showed themselves. Absolute rest, small blisters, and iodides were prescribed The rheumatism soon left him and within five weeks almost all signs of valvulitis had disappeared At this point unfortunately I went away for a fortnight's rest. The patient felt well and he seized the opportunity of my absence to sit up in bed and to indulge in a degree of activity unsuited to his condition On my return I found that a loud apex bruit with accentuation of the second pulmonary sound were again present The most absolute rest was carried out for eight weeks and again the symptoms vanished and now after some weeks further comparative rest the man's heart appears to be perfectly sound. There are no increase of dulness and no dyspnœa on exertion—of course I do not allow much exertion yet—no bruit and no pulmonary accentuation in fact, to all appearance his heart is as sound as ever it was.

CASE 3.—This woman was admitted into the hospital on Nov 22nd, 1901 with acute rheumatism, severe double pneumonia, and right pleural effusion. She was a weak nervous and excitable girl. Her temperature on admission was 103 7° F her respirations were 40 and her pulse ranged from 112 to 140 but was liable on the least excitement to rise to 160 180 or more. Within three days of admission endocarditis became manifest. The pneumonia was severe and unusually long-continued and a lengthy period elapsed before resolution was complete. All trace of dulness did not subside until the first week of February

Her condition was at times so alarming that it was not always possible to carry out the appropriate treatment for the valvulitis On account of the severe cough and the dyspnœa and the persistent rapid pulse I had little hope of curing the valvulitis, and so the event proved, she recovered from the rheumatism and the pneumonia, but with a heart having five and a half inches of deep transverse dulness and loud systolic and presystolic murmurs She died on April 13th, 1902, from heart disease and purpura Our failure to do any good to the valvulitis was probably due to the impossibility of securing the needful degree of rest for the heart.

CASE 4 —This case is that of a private patient whom I have seen in consultation with Dr W Blair Bell Acute endocarditis had resulted from a severe rheumatic attack which Dr Bell had subdued by appropriate measures before he called me in. We decided to treat the valvulitis by the method named above. The results after some weeks were highly satisfactory Then, unhappily, came a change for the worse and the cardiac symptoms recurred. On inquiry as to the cause it was found that though the patient had adhered to the plan of treatment with strictness, circumstances had arisen causing grave anxiety and much mental perturbation, raising the pulse rate and interfering with sleep It appeared that only by removing the patient to fresh and quite tranquil surroundings could this difficulty be met. The change was made and it was followed by speedy amelioration. The pulse rate fell, all signs of valvulitis are disappearing, and in all probability the patient will regain a sound heart. I recite this history because it indicates the need for mental tranquillity

The first two of these cases illustrate in a somewhat interesting manner the evil effect of too early a return to muscular activity and higher blood pressures during the convalescence from valvulitis, the third shows the disastrous influence of rapid heart action and dyspnœa on coincident valvulitis, the fourth exemplifies the evil result of mental agitation on a subsiding endocarditis even though absolute rest of trunk and limb be maintained, and all illustrate the several causes which, unless the physician carefully neutralise them, ordinarily prevent the recovery of the endocardium from rheumatic disease

---

70 CASES OF INGUINAL HERNIA TREATED BY THE KOCHER-BASSINI METHOD,

WITH REMARKS UPON THE TECHNIQUE OF THE OPERATION,

BY J LYNN THOMAS, C B, F R C S ENG,
SURGEON TO THE CARDIFF INFIRMARY, CONSULTING SURGEON TO THE "HAMADRYAD" HOSPITAL PORTH HOSPITAL, BRIDGEND HOSPITAL, AND CARDIFF PROVIDENT DISPENSARY

I DESCRIBED in the *Bristol Medico Chirurgical Journal* for December, 1898, Kocher's method of dealing with the hernial sac in inguinal and femoral hernia. Professor Kocher's latest method had not been described in the English language at that time, and as I had had the opportunity of seeing it performed at Berne I was induced to publish a description of the method when I had only performed it a few times, chiefly on account of its simplicity, novelty, and the apparently sound principle involved in its conception. The description of Kocher's method is practically summed up in the title of the above paper, which was "The Radical Cure of Reducible Hernia by Invagination and the Lateral Displacement of the Neck of the Sac." Since that time I have performed the operation 70 times by the combined methods (1) of Kocher's treatment of the hernial sac, and (2) Bassini's method of restoring the posterior wall of the inguinal canal

I think the combined method of Kocher and of Bassini is the best for the radical cure of hernia when it can be carried out. The two methods are founded upon an unquestionably sound basis, are easy of execution, and have withstood the test of trial. Kocher's forceps for invaginating the sac and pushing it out through the *entire thickness* of the abdominal wall are very slender, and in cases where the sac is not much thickened they can be protruded through the abdominal wall without the aid of a scalpel, when the sac is very large and thickened one is called upon to facilitate the egress of the invaginated sac by making a small incision upon the projecting forceps and sac In some cases where the sac is very massive I think it is inadvisable to invaginate the sac, but that it is better to ligature it at the neck, to cut the sac off, and to pass the ligature by means of Kocher's sac forceps under the abdominal muscles for about two or three inches and to bring it out through them, hauling up the sac as far as it will go and fixing the ligature to the external oblique or to the semilunar line In one of my 70 cases there was an interstitial hernia and in obliterating the space I placed three rows of buried sutures between Poupart's ligament and the posterior wall of the cavity

Suture material —I believe that non absorbable ligature is the best material for permanency of cure, for the very safety of the patient during vomiting or coughing immediately after an operation depends upon the approximating sutures. Sutures do not cut out their way through tissues they bring together (especially fibrous structures), surely when scar tissue has formed (which, by the way, has a tendency to stretch as well as to contract) the presence of the unyielding silk fibres must be a source of additional strength against stretching to the scar fibres I always use fine silk (No 00) either as a continuous suture or an interrupted suture closely applied with a curved needle of small calibre and with a blunted point, similar to a rug needle or a saddler's stitching needle, according to conditions I consider the ordinary hernia needle too coarse an instrument as it makes too big an opening in the tissue to be sutured together The only advantage that I can see in an absorbable ligature is for cases where the surgeon is worried by suppuration.

Pyrexia in aseptic cases —There was no drainage used except in one case where a large hydrocele was excised at the time of the radical cure. In four cases there was pyrexia to 101° F and in one case the temperature rose to 103° after the operation, but resumed the normal about the fourth or fifth day In most of the cases the rise of the temperature was due either to effused blood or to hydrocele fluid bathing the field of operation, as several hydroceles coexisted with the hernia and were treated simultaneously The temperature was a straight line in all cases except where there was an additional operation for hydrocele or where a hæmatoma formed.

Truss —I always advise patients not to wear a truss after operation, unless in exceptional cases where the abdomen is flabby, thin, or atrophied, and in such cases a good abdominal belt suffices. I operated upon a patient under the care of my friend Dr Arthur E Taylor in February, 1901, a few hours after a hernia became strangulated, and in the following summer the patient played cricket vigorously throughout the season in county matches and is at present quite sound. The wearing of a truss for a number of years has sometimes an injurious effect upon the abdominal wall as well as upon the hernial sac, which becomes firmly adherent to surrounding structures and cannot be properly isolated so that a Kocher's operation may be performed upon it, in such cases I generally close the posterior wall of the inguinal canal and treat its anterior wall by Lucas Championnière's overlapping method. In congenital hernia it has been my experience that it is only occasionally that one can perform the invaginating operation.

Removal of sutures from the skin —It is very important to know the nature of a patient's skin in order to avoid "stitch abscess," which in hernia operations with a hæmatoma following would be a source of considerable risk. Cases of failure of cure that I have seen are those that have suppurated In tender, eczematous, or coarse skins it is advisable to take the skin sutures out at the end of 24 hours I am inclined to think that all suppuration can be prevented by very simple means in this branch of surgery Two of my cases suppurated, the one when I closed the skin with an absorbable ligature and in which I had hoped to dispense with the one dressing which is done when I take out the sutures. Alas, I was disappointed and the absorbable ligature caused me just enough worry to make me determine never to try it again The other case of suppuration followed a case of operation for a strangulated hernia in which I believe I ought to have drained for a day or two instead of closing without drainage.

Dressing —The only dressing used after operation has been six layers of gauze kept on by a wider layer of gauze fixed by collodion. I do not use bandages.

Cardiff

ON SOME CASES OF OPERATION FOR *CHRONIC NON-MALIGNANT DISEASE* OF THE STOMACH.

BY ARTHUR E. BARKER, F.R.C.S. ENG.,
PROFESSOR OF SURGERY AT UNIVERSITY COLLEGE AND SURGEON TO UNIVERSITY COLLEGE HOSPITAL.

A REVIEW of a series of more or less similar cases occurring within a given period is always interesting and profitable, and I propose to glance back at a group of non malignant cases of chronic gastric disease treated surgically which have been under my care comparatively recently—all since this time last year. Such a retrospect enables us in the first place to contrast allied affections of the same organ in their causation, symptoms, and effects. In the next place it gives us a good opportunity of examining into the forms of treatment which have been found most effectual. The present series is a fairly complete one of its kind. It includes only those cases of non malignant chronic inflammatory disease of the stomach and duodenum on which I have recently operated, and it includes them all, the series is consecutive. The accompanying short table gives an epitome of the group and enables us in a moment to see the class of affections we have been dealing with and the leading features of each:

Consecutive Operations for Chronic Non-Malignant Disease of the Stomach and Duodenum.

Number of case.	Sex, age and duration of illness	Condition before and after operation.	Result.
1	M., aged 48 years. Illness of six years duration.	Duodenal ulcer with severe hæmorrhage from bowel. Also severe pain after food. Emaciation. Weight before operation, 8 st. 9½ lb. When last seen health was excellent. Weight 10 st.	Recovered.
2	F., aged 48 years. Ill for six years.	Gastric ulcer; "hour-glass" contraction; extreme emaciation. Weight before operation, 6 st. 10 lb. When last seen health was excellent. Weight over 9 st.	*Recovered.*
3	F., aged 66 years. *Ill for* one and a half years.	Pyloric stenosis due to ulcer. *Emaciation; pain.* Weight before operation, 8 st. 12 lb.; some time before was 10 st. 2 lb. When last seen health was excellent; weight had increased.	Recovered
	M., aged 45 years. Ill for three years.	Pyloric stenosis due to chronic ulcer. Pain, vomiting and emaciation. Weight before operation, 9 st. 9 lb. 12 oz.; nine months later weight was 10 st. 16½ lb.	Recovered.
5	F., aged 24 years. Ill for three years.	Bleeding gastric ulcer. No stenosis of the pylorus. Repeated hæmorrhages pain and vomiting. Not any emaciation, but much tenderness over fundus of the stomach. Weight before operation 8 st. 9 lb.	Recovered.
6	M., aged 33 years. Ill for four years.	Pyloric stenosis from ulcer. Pain, *vomiting, tenderness and emaciation.* Weight before *operation,* 9 st. 2 lb.	Recovered.
7	M., aged 47 years. Ill for 15 years.	Pyloric stenosis due to gastric ulcer. Pain, vomiting, great dilatation, *gastric tetany and rigors,* and emaciation. Weight before operation 7 st. 12 lb.	Recovered.
8	F. Ill for 10 years.	Pyloric stenosis from ulcer; scar band. Moderate emaciation pain, vomiting bleeding by bowel, and tenderness over fundus of the stomach.	Recovered.
9	F., aged 35 years. Ill several years	Pyloric stenosis with lump about the pylorus of doubtful nature. Extreme emaciation. Weight before operation 4 st. 3 lb.	Recovered.
10	F., aged 62 years. Illness of 10 years duration.	Pyloric stenosis due to small ulcer. Great exhaustion and emaciation [illegible] vomiting	Recovered

Let us look a little more closely into these points. In the first place, all, with two exceptions, required treatment on account of obstruction to the escape of food from the stomach into the intestine. The two others claimed interference on account of chronic ulcers, in the one case of the stomach and in the other of the duodenum which ulcers were bleeding to a disquieting and perhaps dangerous degree for long periods lasting over years in spite of good treatment. But apart from this symptom there was the danger that at any time either of the ulcers might perforate into the abdominal cavity and lead to disastrous effects.

In the cases of stenosis one showed the effects of a chronic ulcer upon the body of the stomach, contracting it into an "hour-glass" cavity which could not properly be emptied into the duodenum; the others were all instances of con*traction of the pylorus itself* in which either the contraction would be seen in the shape of a puckered scar through the peritoneal covering or felt by the finger pushed into its ring *by invaginating the wall of the stomach (Hahn).*

With the epitome before us it is hardly necessary to describe any case in detail. It will be more profitable *to review* the causation symptoms, and effects practically common to all. All the cases of stenosis began with the usual symptoms of dyspepsia—i.e., discomfort or pain after food, followed sooner or later by vomiting *of undigested matter and* usually by *more or less bleeding.* Then, under restricted dieting and other more direct medical treatment remissions took place and often considerable improvement, so that but little discomfort was felt. But then, in all these cases at least, a return of the trouble occurred on resumption of the ordinary dietary. This was again met by the usual treatment of dyspepsia with the addition in the later cases of washing out of the stomach some hours after food. This last means of relieving the *stomach* of its residuum of *fermenting food has proved* a most valuable *addition to the treatment of those cases* in which either a chronic ulcer was present or the result *of such an ulcer in the form of* a contraction of a part of the stomach or pylorus. And it appears probable, from what we have seen in those and many other cases, that were washing out more frequently employed in the various forms of chronic dyspepsia as a regular treatment we should see less of the evil effects of acute and chronic gastric ulcer. But in the later stages of gastric disease where an ulcer is becoming chronic and is producing *stenosis it can only of course, be regarded* as a valuable palliative and again as a useful preparation for operative treatment. The cases in this list, although several of them were thus treated by lavage for long periods, were so chronic that a permanent cure was not effected in any.

Another symptom was present in *most of the cases*—namely dilatation, more marked, of course, in those who came to us after little or no preliminary treatment than in *those who had been kept on restricted* and suitable diet. It is quite plain that dilatation of the stomach can be more or less prevented by careful diet, so long as there is even a small outlet for the food from the stomach. It is only where the latter is almost absent that the dilatation is extreme. But it must not be forgotten that besides actual organic contraction of the stomach or pylorus the outlet may be contracted by the sphincter action of the pylorus induced by irritation of improper or fermented food with or without an excoriation or ulcer of the ring. In these cases the regular removal of an undigested residuum from the stomach some hours after meals eliminates the source of irritation and gives the *pylorus rest. This is productive* of the most marked immediate benefit and *may even if regularly* carried out, result in a return to nearly normal conditions in the pylorus by removing the irritant regularly and giving the ulcer or *abrasion* complete rest for hours at a time, during which the sphincter is relaxed, for it must never be forgotten that one of the functions of the pylorus is to prevent improper food or ill-digested material from gaining its way into the small intestine. For this reason all semi putrid material in a dilated stomach is prevented by spasm of the sphincter pylori from entering the duodenum.

The dilatation of the stomach in these cases has been estimated in the first place by percussion. This, however is clearly an unsatisfactory method of testing the size of the organ if taken alone. *If the stomach* contains much gas its size is easily demonstrated by percussion. But in many of these cases there was but little gas to a large quantity of fluid and undigested food. I therefore make it a rule in all these cases to test the point of dilatation first by percussion, then by observing how much is drawn off from the organ by syphon, next by filling the stomach again with water until discomfort is produced and measuring the quantity which can now be withdrawn, and finally by inflating the now empty organ with a Higginson's syringe and percussing it out again This can all be done quickly and without much distress while at the same time the washing out is beneficial. In the penultimate case operated on the dilatation when gentle injection of air was used was seen to be extreme and the border of the organ could be distinctly made out through the very thin abdominal walls as a ridge sweeping in a long curve some inches below the umbilicus This method of injection of fluid or air has a further aim It enables us mainly to estimate the muscular power of the stomach—in other words, whether there is hypertrophy of its muscular walls or an atonic condition combined with dilatation. This point is of importance If the fluid is returned with force it indicates, in the first place, that obstruction is probably marked, but that after a gastro enterostomy a rapid return to the normal may be expected But if the fluid in a largely dilated stomach is returned with very little force or has to be syphoned off there may be stagnation in the organ from atony even after such an operation, and it may be better to postpone the latter until, by a course of washings and tonics, the organ is more or less restored to its normal contractility For nothing can be worse for the chances of good union between the stomach and intestine than the stagnation of blood, mucus, bile and swallowed food around the new opening

In the two cases in which gastro-enterostomy was done on account of hæmorrhage there was no dilatation when seen by us The patients had been suffering from vomiting of blood on and off with pain in the one case for three years and in the other for six years, with passage of large quantities of blood by the bowel. Both had pain after food. These symptoms were only partly relieved by treatment in this hospital and elsewhere and always recurred on remission of medical treatment and return to anything like normal diet The fear in these cases was either that the bleeding would prove fatal or that perforation would sooner or later take place unless the stomach was regularly relieved (one was an ulcer in the duodenum) Almost all these cases then had had careful medical treatment before the question of surgical interference was entertained.

The preparation for the latter was the routine one with me. It consisted in the cleansing of the stomach for several days by washing and the administration of only small quantities of sterile fluid food The mouth was at the same time cleansed and carious teeth were extracted. This I hold to be of the utmost importance Concurrently the patients were given 10 grains of carbonate of bismuth three times daily as an intestinal antiseptic and the lower bowels were washed out with enemata. Where great emaciation was present the normal amount of water was given to the tissues by hypodermic instillation of normal saline solution, a pint morning and evening, and to this I have added 5 per cent. of glucose with much benefit Nutrient enemata were also the rule for days before. When by these means the stomach had been cleansed and the forces of the patient recuperated, after thorough antiseptic cleansing of the skin the operation was carried out as rapidly as possible with the exclusion of strong germicide from all contact with the abdominal contents. The operation in all these cases was done without Murphy's button or any appliance of the kind In every case it was the retrocolic variety (v Hacker) The suturing was done in the same way as in my first case 15 years ago—namely, by uniting the serous and muscular coats behind the proposed opening, before the latter was made, and then by opening the gut and stomach and uniting the resulting edges and finishing the continuous suture over the front which had been begun before the viscera had been opened When I published this method 15 years ago I did not know that it would become the classical one, as has been the case The abdominal wound was closed in every case except one by sutures, including all the layers with the skin Oddly enough, in the exception in which buried sutures were used in addition to skin stitches the whole wound yielded on the tenth day after the latter had been removed from a flawless primary intention wound. The same evening the wound quietly gaped during a trifling movement of the patient in bed. Four days later I found the wound widely open on removing the dressings and the omentum and small intestines exposed. The patient, however, was in excellent condition and with a normal temperature. The edges of the wound were covered with lymph and a little fresh blood clot, there was no trace of pus I simply scraped off the lymph, wiped the edges dry, and sutured through the whole thickness of the abdominal wall, removing the old buried sutures at the same time The wound healed as thoroughly as if by first intention and the scar was quite sound when the patient left the hospital.

In the course of operations such as those applied to these cases there are countless small details upon which their success greatly depends but which I should find it very difficult to describe adequately and at the same time briefly They can only be learned by close attention to every step of the procedure. Fortunately, these cases have followed each other so steadily and closely that those who attend our hospital have had every opportunity of becoming familiar with them and I need attempt no detailed description of them.

There remain then, to be considered only some points in regard to the after treatment of these cases of non malignant pyloric stenosis in which posterior gastric enterostomy has been done In the first place, while on the operating table if there were any signs of shock the patient received in the areolar tissue of the arm near the axilla a pint of the saccharo-saline solution This and the maintenance of the body heat by hot-water bags and wrapping in cotton wool was found quite adequate in all to prevent the evil effects of shock which was hardly seen in any, even the most asthenic On being removed to bed the patients were placed on their backs, at first a little inclined to the right. As soon as they wished (generally the second day) they were kept in the semi recumbent position while awake and were laid on their right side for sleep or change of position All this seems to have several advantages. In the first place, whatever fluid is in the stomach, be it bile, blood, or food, and mucus, appears more readily to find its way into the new outlet of the stomach than when the position is directly flat on the back. Then there is less chance of œdema of the lungs when the thorax is semi erect. Again, the occasional change of position with these patients suffering in most cases from the most extreme emaciation, is the surest way of warding off bedsores and securing comfortable sleep But doubtless the most important factor of all is the increase in the capacity of the chest as the abdominal viscera sink downwards in the almost vertical position of the trunk Lung troubles are, as we know, the bane of abdominal operations and without going into all the theories as to their causation it must be admitted that restriction of the free movements of the thorax contribute at all events to their danger

The next point worth noting is that all these patients have been fed from the first by the mouth as well as by the rectum. As soon as it has been clear that chloroform nausea was not present or passing off they have had albumin water with a drachm of brandy at first half an ounce every two hours, then every hour and then double the amount until about the fifth day they were ready for Benger's food, pounded fish, or chicken.

A further matter attended to has been the tendency in many cases to regurgitation of bile into the stomach during the first few days when it may produce a sense of weight and discomfort or induce vomiting This was shown by Carle and Fantino to be almost the rule in such cases, even when patients were almost unconscious of it In almost every one of these cases, then, I have introduced a rubber tube into the stomach during the first 24 hours with a view to relieving the organ of bile with blood and mucus, which is usually there and may be decomposed if left there. And I have been astonished in several cases at the amount of fluid lying stagnant in the organ after operation and also at the amount of relief given. So great is the latter that patients who have once had the tube will assent to it again if they do not actually suggest it. There has been very little need in these cases, as a rule, of washing out the stomach at the same time that the fluids have been syphoned off. But in some cases, especially where there was oozing of blood from the stomach and intestinal wounds, washing out with boric solution or mere normal saline solution has appeared to be beneficial All the wounds have healed blamelessly But in one, as already mentioned, in a man suffering from the most extreme emaciation, the scar opened on the tenth day and had to be re-sutured Not the slightest ill result followed.

As to the results, all have recovered and the change in health in those who have had time to show it has been most remarkable. The patients have all increased in weight and lost all their other symptoms. It is quite clear to me now that in such cases of non malignant stomach disease lasting for years in spite of skilled medical treatment the formation of a short cut between the fundus of the stomach and the upper part of the jejunum offers a very good prospect of complete relief and with a very moderate risk And as the principles underlying these operations are better understood and our technique improves in detail these risks cannot but become less and less to judge by the history of other operations.

30 CASES OF GASTRO ENTEROSTOMY FOR NON-MALIGNANT AFFECTIONS OF THE STOMACH[1]

BY T KENNEDY DALZIEL, M B., C.M. EDIN
F F P S, GLASG
PROFESSOR OF SURGERY ANDERSON'S COLLEGE, AND SURGEON TO THE WESTERN INFIRMARY AND ROYAL HOSPITAL FOR SICK CHILDREN GLASGOW

THE operation of gastro-enterostomy has so long since passed the region of experiment that at this date it is hardly necessary to enter into the question of its propriety in suitable cases. Of course, the object of the operation is to enable the stomach to empty its contents into the intestine in cases where, from organic or functional causes, that does not occur with sufficient readiness to prevent fermentation, in consequence of which a state of irritation is induced in the mucous membrane of the stomach as well as a general deterioration of health from starvation and the absorption of toxins. Of the utility of the operation in pyloric obstruction simple or malignant, there can of course, be no doubt whatever and it seems to me that much benefit may be obtained in cases where the normal action of the stomach is prevented or at least materially retarded by adhesions either in the region of the pylorus or over the general surface of the organ due in many cases to plastic peritonitis from a perforating gastric ulcer or to pathological changes in the neighbouring viscera. It is probable that in another group of cases due merely to functional disorder where we have dilatation of the organ without obstruction at its outlet, but accompanied by the usual fermentative changes we have in gastro-enterostomy a means of draining the organ and thereby of alleviating the misery which has been found by the physician to be unrelieved by any ordinary method of treatment. No doubt the operation would be most useful and most frequently *practised in those cases where there are marked organic* causes leading to dilatation The establishment of the operation as a useful and trustworthy means of treatment will necessarily depend upon the mortality which accompanies it

I beg leave to bring before this section a group of 30 operations undertaken for the cure of apparently incurable dyspepsia, many of them with evidence of marked pyloric obstruction The patients had been under treatment prior to operation for periods varying from two to 17 years 16 of them with definite history of ulceration At the operation it was found that 18 of these cases presented well marked contraction of the pyloric orifice and in two cases this was so extreme as practically to amount to occlusion, so that it had been found necessary to wash out the stomach two, and occasionally three times a day to render life tolerable and from the history it was evident that little or no material entered the intestinal canal The degree of contraction was estimated by examination from within the stomach. In eight cases the obstruction was due to adhesions the result of peritonitis originating from old tuberculous glands behind the pylorus these adhesions so compressing and kinking it as to interfere with the emptying of the stomach. In three cases the posterior wall of the stomach was found adherent to such an extent as to interfere with its muscular action and in one of these the adhesions were so extensive and their contraction was so considerable that the pylorus was pulled backwards and to the left side so that it simulated a tumour of the splenic flexure of the colon for which, indeed it was mistaken prior to operation. In one case there was marked dilatation of the stomach without any apparent physical cause Many of these patients were in a state of great emaciation from prolonged malnutrition: In three of the cases of external adhesions I had previously operated with only temporary relief after their separation—an experience which seems to be not unusual indeed I find that of seven cases in which I have divided adhesions only one remains permanently benefited so that I am inclined to think that in such cases it is better to put the stomach at rest by the performance of a gastro-enterostomy

The symptoms presented by the individual cases were as usual varied and variable, as was also the amount of dilatation In all the misery and suffering were sufficiently great to render the patients very willing to run the risk of the operation with prospects of relief In those cases where the trouble was located not in the pylorus itself the dilatation was naturally least, and in four of these cases did not indeed exist to any extent, although all the symptoms of an obstructive dyspepsia were present. No doubt the amount of dilatation in many of these cases had been kept in check by regular lavage of the stomach practised in periods varying from two months to three years. In almost all the cases pain was a prominent symptom and indeed in four cases while there had been no vomiting except on very infrequent occasions, the pain was so persistent and intense, and so utterly unrelieved by medicinal treatment, that an exploratory incision was advised and a physical condition was found which warranted the gastro-enterostomy being performed.

As a preliminary to operation careful lavage of the stomach was carried out in all cases for two days before the operation, plain water being used and great care being taken thoroughly to empty the stomach immediately before operation. With all the ordinary antiseptic precautions an incision was made above the umbilicus, in the earlier cases through the middle line but later through the middle of the left rectus muscle. With the exception of four cases all the operations have been that of posterior gastro-enterostomy the anterior being performed in one case by selection and in the *others being rendered necessary by the presence of* extensive posterior adhesions which rendered it impossible to gain access to that surface of the stomach

The usual method of operation has been to withdraw and turn up the omentum and colon guarding these with large, flat, natural sponges wrung out of sterilised saline solution. The posterior wall of the lesser peritoneal bag is opened with a cut from the scissors and this wound is stretched sufficiently to allow a portion of the stomach, preferably near the junction of the pyloric with the middle third to be drawn through, so that the opening may be situated high up—that is towards the lesser curvature A loop of the jejunum, readily found by looking for the termination of the duodenum is then withdrawn and approximated to the selected portion of the stomach and fixed to it by means of hook forceps about two and a half inches apart, so that ample room may be left for the stitching In all cases three rows of continuous sutures were inserted : the first, that to be furthest from the opening being of silk the second of catgut which may absorb in from four to six days and the third next to the lumen of the canal, of fine intestinal silk—the idea of the intervening catgut being to secure a zone of adhesions without the prolonged presence of a foreign body so that the outer retaining suture may be less easily contaminated by sepsis from the necessarily exposed wound of the mucous membrane. *After the first two rows of sutures have been inserted half way round that point where the opening* is to be made they are carefully guarded with sterilised gauze and the jejunum is opened in its long axis opposite to the attachment of the mesentery and a corresponding opening is made in the long axis of the stomach. These openings have generally been about two inches in length. All bleeding points are carefully ligatured and while this is being done plugs of gauze are inserted into both openings to prevent escape of contents which for the most part consist of mucus and bile But rarely has this given rise to any trouble, since the parts can be held up sufficiently to prevent overflow Finally the third row of sutures including all the coats is inserted quite close to the gut wound and thereafter the second and first rows are carried round to where they started The opening in the omentum is then carefully adjusted round the anastomosis and the parts are returned to the abdomen, the abdominal wound being closed in the usual way, preferably by suturing in layers, and in addition by a number of sutures transfixing the entire thickness of the abdominal wall.

---

[1] *A paper read before the Surgery Section of the British Medical* Association at Manchester on August 1st 1902.

As to the immediate after effects of the operation, in no case has there been shock of any consequence, and but rarely has the temperature risen to 100° F, and that only during the first 24 hours Sickness, persisting for some days after the operation, has been noted as occurring most frequently in women, and in only two cases has the bilious vomiting persisted beyond the third day, and in the last 12 cases with one exception, there has been no bilious vomiting whatever—a happy result which I am inclined to credit to leaving the jejunum slack by forming the attachment lower down than formerly and probably by placing the opening higher up in the stomach. In one case I performed a double anastomosis, as practised by Mikulicz, but the result was not encouraging As soon as the sickness of anæsthesia passes off the patient is allowed water and barley water freely and as soon as inclined a copious supply of chicken tea and diluted peptonised milk, so that by the fourth day from three to four pints of liquid nourishment are being taken and at the end of eight or 10 days light puddings and pounded meat. In one case there was a threatening of enteritis The patient had been confined to her bed for the greater part of two years and the pylorus was found to be practically occluded, so that little or no nourishment passed from the stomach into the intestine, which was found to be so thin as to render its suture to the enormously hypertrophied stomach wall a matter of great difficulty Within a fortnight, however, by very gradual and careful gradation of feeding, this patient overcame the tendency and is now a vigorous, robust woman Two cases occasionally had bilious vomiting, one after the lapse of three months, the other after one and a half years, but this happened so seldom and gave rise to so little trouble, only occurring in the morning before food had been taken, that the patients practically ignored it.

In regard to the ultimate results of the operation, of these 30 cases of gastro enterostomy for non malignant disease of the stomach I lost one, and that is naturally the most important case of all for our consideration. The post mortem examination showed a condition of things rendering the fatal issue a not improbable one. The patient, a man, aged 54 years, had suffered from his stomach for seven years and for the previous eight months he had used a stomach tube each day to relieve the oppression and flatulent distension His story was that from four to five hours after a meal he had great pain near the pit of the stomach which was relieved often by lying down and by taking more food He rarely vomited and only once was there any trace of blood in the vomited material. Examination showed that the stomach was markedly dilated, passing below the umbilicus No definite tender spots could be felt and there was no tumour or pyloric thickening Hippocratic succussion was manifest but there was no peristaltic wave. A test-meal of one pint of milk, half a pound of boiled fish, and a slice of toast was given, and three and a half hours afterwards it was found that the stomach contained seven and a half ounces of fluid with an intensely sour smell, due to the presence of organic acids, there being an almost complete absence of hydrochloric acid These observations were made by Dr John S McKendrick, who diagnosed the case as one of gastric catarrh, with distinct dilatation, probably atonic in character The patient was put on a special diet, with a tonic containing dilute nitric acid, nux vomica, and pepsin, with, in addition, hyposulphate of soda between meals For a time he improved and gained in weight but the pain returned. When I saw him with Dr McGregor Robertson and Dr McKendrick on Sept 11th, 1901, nothing was found on examination under chloroform suggesting a tumour or pyloric thickening It was determined that laparotomy should be performed and on Sept. 27th operation revealed three adhesion bands passing from the under surface of the liver to the duodenum, tucking it up so as practically to kink the pylorus He obtained great relief from this operation and continued well for some time, being able to eat heartily, so much so that his wife stated that he ate occasionally a whole rabbit for his lunch At the end of the year, however, the pain returned and with it a very great amount of abdominal distension. This pain differed from anything he had had previously, it seemed to be located in the neighbourhood of the left kidney and extended into the iliac fossa. At the urgent request of the patient it was agreed to reopen the abdomen, which was done on Dec 19th, when it was found that the old adhesions had re united, and in addition a mass was found in the posterior wall of the stomach, fixing it posteriorly When the stomach was opened it was found that there was in this mass a circular opening with firm thickened edges and with a deep, crater-like ulcer in the centre of a large mass of tissue An anterior gastro-enterostomy was performed, although with considerable difficulty on account of the extreme flatulent distension of the intestine After the operation everything went well. Although the distension persisted it did not increase, nor did the pulse increase in frequency, remaining as it was prior to operation, between 80 and 90, so that on the third day he expressed himself as remarkably comfortable, and when last seen by me he was reading the morning paper The following day, however, the patient complained of sudden acute pain in the wound, and on my assistant removing the dressings a small protrusion of intestine was found between two stitches about three-quarters of an inch apart. One of these was immediately removed and the intestine was replaced, but the patient died from shock within two hours Post mortem there was found no evidence of peritonitis. The suturing had remained firm and was quite satisfactory, but that which we had supposed at the time of operation to be a large malignant growth extending and breaking down proved to be an unusually large simple ulcer, the whole of the stomach walls being destroyed, for a circular area about two inches in diameter, exposing thereby the inflamed and thickened pancreas, the fibrous tissue of which was evidently being digested, so that only the secreting structures remained This, then, is the only death out of 30 cases, and I feel that while the operation led to the fatal result that result is to be ascribed to the complication which existed and which would have had the same ending had laparotomy been done for any other disease The sutures between which the protrusion took place were not more than three-quarters of an inch apart and transfixed the whole of the abdominal wall. The case is otherwise an extremely interesting one in view of the involvement of the sympathetic plexuses with the consequent peculiar distribution of pain and intestinal paresis

In regard to the ultimate result of the cases it is as yet too early to speak in the more recent ones, though, with the exception of two cases operated upon for very widely diffused adhesions round the stomach, and one case where no organic cause was found for the intense gastric trouble, all the others have proved, on the whole, extremely satisfactory, particularly so in those cases where the patients had previously suffered from marked obstruction in the pylorus itself. In 18 of these cases the patients state that they are as well as ever they were in their lives. Although there may be a natural tendency to exaggerate on their part, there is no doubt that they have been relieved from their distressing symptoms and have materially gained in weight—in one case from five stones 11 pounds to 11 stones within a year after operation Three of the patients state that while there has been improvement they still suffer from pain, though life is now tolerable The remaining nine express themselves as very well indeed, although they have to be careful in their dietary and occasionally suffer from attacks of flatulence

It is not within the scope of the present contribution to compare this operation of gastro enterostomy with other operations for the relief of dilatation, but I believe that in this operation we have a means of relieving a vast amount of suffering, and, what is of equal importance, of returning to the body politic many useful and valuable lives otherwise doomed to suffering and misery, and this with an amount of risk to life much less than is daily undertaken for less serious ailments I therefore beg to add my experience to the brilliant results already published by Mikulicz, Kocher, Robson, Barker, Moynihan, and many surgeons in this and other countries, whose results prove equally the safety, necessity and efficiency of the operation

In comparison with operation for malignant disease of the pylorus it has been my experience that the operation, if done early, is not attended by much more risk than when done in simple cases I have operated in very advanced cancer in four cases with the hope of alleviating the final sufferings but the result has not been encouraging

Glasgow

A CASE OF POST-OPERATIVE HÆMATEMESIS

BY ARTHUR H. BUCK, F.R.C.S. EDIN.,
ASSISTANT SURGEON, SUSSEX COUNTY HOSPITAL; SURGEON, BRIGHTON AND HOVE THROAT AND EAR HOSPITAL.

THE following case, which I saw with Mr. E. H. Sweet of Uckfield in April of this year and afterwards operated on is, I think, of interest, as the records of similar cases are not numerous.

A spinster aged 53 years had suffered from pelvic pain, menorrhagia, and metrorrhagia for 23 years. On May 6th ether having been administered by Mr. Morris Rigby, the abdomen was opened and the patient was placed in Trendelenberg's position. The pelvis was found to be occupied by an adherent mass consisting of (1) the Fallopian tubes dilated to the size of small intestines and coiled over and amongst the other structures; (2) a left ovarian cyst of the size of an orange and adherent to the anterior surface of the uterus; (3) the right ovary small and atrophied; and (4) the uterus, which was completely retroflexed and presented in its posterior wall a fibroid as large as a cricket ball. These structures were firmly adherent to one another, to the bladder in front, and to the rectum behind. The broad ligaments were indistinguishable and on removing the left tube the ureter on that side was exposed for four inches. After considerable difficulty the pelvis was cleared and flaps of peritoneum were sutured so as to leave a smooth walled cavity. The operation was necessarily a severe one and lasted for two hours. Mr. Sweet kindly and most ably assisted me.

During the first 36 hours after the operation there was considerable abdominal pain and sickness occurred several times. Morphia, to which the patient was accustomed, was administered hypodermically three times in quarter grain doses. Flatus was freely passed and the abdomen was never distended, nor were the abdominal walls fixed. The pulse-rate did not exceed 88 and the highest temperature was 100° F. 36 hours after the operation the patient vomited a large quantity of altered blood (coffee coloured) and a second similar quantity four hours later; the temperature fell to subnormal but the pulse was not affected. Mr. Sweet prescribed a lead and opium pill, and the following day, as the vomiting of blood attended by very severe retching continued, four doses of liquor chloride of adrenalin were administered hourly, the first two doses consisting of 30 minims each and the last two of 10 minims. Mr. Sweet also gave four grains of calomel, followed by two grains of calomel twice at intervals of two hours, producing a good action of the bowels. After this there was no further vomiting of blood although extremely violent retching persisted with the result that the fine silk used for suturing the sheath of the rectus gave way at the upper part of the wound and intestine protruded on the fourth day. Under chloroform the wound was re-closed with silkworm gut sutures. During these four days nutrients were retained, flatus was passed, the bowels acted on the second day after turpentine enema, and on the third after calomel. The pulse rate did not exceed 100, neither did the temperature rise above 100°. The patient then very rapidly picked up and made an excellent recovery thanks to her nurses and medical attendant, and is now perfectly well.

Mr. A. W. Mayo Robson and Mr. B. G. A. Moynihan in their recent work "Diseases of the Stomach and their Surgical Treatment," refer to several cases of post-operative hæmatemesis of which four were fatal. In THE LANCET of Oct. 20th, 1900, p. 1125, three cases were reported and a fair number of others have been published. The operations after which the complication has been noticed have been various, as have been the causes to which the hæmorrhage has been attributed. The view that Mr. Mayo Robson and Mr. Moynihan take, that it is due to a reflex nervous action, would fit in well with the above case, as the severity of the operation and the removal of both ovaries and uterus would no doubt upset, if any operation will, the equilibrium of the sympathetic nervous system.

I would add that this complication is evidently more likely to occur in those whose blood coagulability is below par and it is interesting to note in connexion with Professor Wright's statements with regard to urticaria and weakened power of blood coagulability that this patient has suffered from urticaria off and on since she can remember and that this has greatly improved under treatment by calcium chloride.

Brighton.

METHODS OF UNITING DIVIDED INTESTINE,

WITH SPECIAL REFERENCE TO A NEW BONE BOBBIN FOR THAT PURPOSE.[1]

BY E. STANMORE BISHOP, F.R.C.S. ENG.,
HONORARY SURGEON TO THE ANCOATS HOSPITAL, MANCHESTER.

METHODS of union are divisible into four main classes: (1) simple suture; (2) suture on moveable forceps; (3) suture on absorbable material, usually decalcified bone; and (4) metallic couplers.

In simple suturing probably Lembert's suture holds the first place, although the principle upon which it is based, the advisability of non perforation of the mucous membrane, is not now so firmly held as it was at the time I first advocated a suture which penetrated the entire wall. A similar method has lately been widely adopted in America. In all cases, even in some of those treated by the fourth method, suturing of some kind is necessary.

Suturing on moveable forceps, as those of Laplace and O'Hara, is easy and rapid, but they have the defect that no protection from the entrance of fæcal matters between the lines of union is afforded by them during the dangerous period immediately after operation. I am not sure that the crushing of the ends produced by their use is directly harmful, since it should be an advantage if these ends, which form an internal flange, afterwards could be removed by necrosis, provided always that such necrosis went no further. Judging by analogy, however, from the recorded results of pressure necrosis produced by Murphy's button, this is not always to be implicitly relied upon.

Metallic couplers, of which Murphy's is the type, have the great advantage of rapidity in application, an advantage which I believe must always render it unlikely that they can be entirely set aside, but so many cases are now to be found in the literature of the subject in which unpleasant later results have occurred that I conceive that they should never be chosen unless the element of time is of the first importance. Progressive necrosis of the gut starting from the line of union and spreading towards some unprotected point, absolute later obstruction, retrograde movements, as backwards into the stomach in gastro-enterostomy, and other incidents of a like kind increase unnecessarily the anxiety of the operator and endanger the final successful result.

There remains the method of suture over some absorbable material. This has great possibilities. Its advantages are that (1) complete and satisfactory suturing is more easily and thoroughly carried out over its resistent surface; (2) it protects the line of union from infective material until such union is complete; (3) it maintains patency and decreases the possibility of post-operative stricture; and (4) when the period of its usefulness is over it disappears. But in order to obtain the best results from it it should possess the following qualities: first, it should be easy of introduction; secondly, it should be perfectly simple and require no elaborate technique; thirdly, it should be resistant and absorbable; fourthly, it should be so made that the purse-string sutures which encircle the ends of the gut should, as they are tightened, approximate these ends by the mere act of tightening; fifthly, when in position it should present the folds of intestine which have to be united by a second line of suture in such a way as to facilitate that suturing; and sixthly, it should be of such a size and shape as to protect the line of suture during the period of plastic union.

Examination of the bone bobbins available at the present time shows that whilst all possess one or other of these characters not one combines them all. The bobbins in use at present are known by the names of the operators who have devised them. They are Jessett's, Allingham's, and Robson's. Jessett's possesses the first, third, fifth, and sixth. It is wanting in the second and fourth. Allingham's possesses the second, third, fourth, and sixth It is without the first and fifth Robson's possesses the first, second, third, and sixth It makes no attempt to supply the fourth and fifth. The bobbins which I bring before your notice attempt to supply them all. It is for others to say as to how far they succeed As will be seen, they present the bevelled conical end which makes Jessett's pattern so easy to introduce, but they are in one piece and do not require the method of fixation to each end of the bowel which he describes[2] In the centre there is the essential portion of Allingham's bobbin, the double inclined plane, tightening over which approximates the bowel ends, whilst the combination of these two produces a short fold in the intestine on either side which is easy to unite by Lembert's or a continuous suture, thus burying the two tied down extremities.

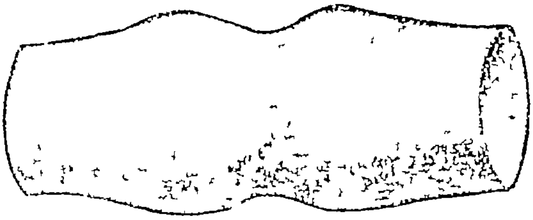
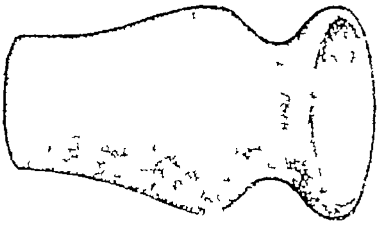
[1] Abstract of a paper communicated to the British Medical Association meeting at Manchester, July, 1902.

FIG 1.



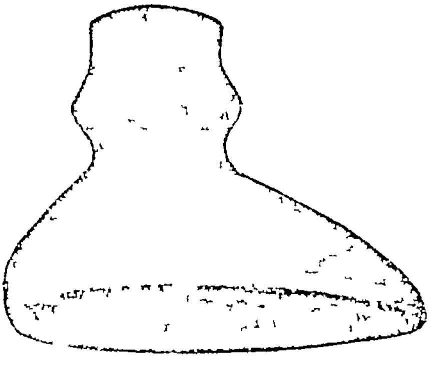
Enterectomy

FIG 2.



Gastro-enterostomy ileo-colostomy

FIG 3.



Pylorectomy

But no one form is the best for all the various operations which are now practised upon the alimentary tract, though all forms should be only modifications of the central idea. I present three, one for ordinary enterorrhaphy, end to end, one for ileo colostomy or gastro-enterostomy, which, as you will notice, is simply the first tube with the end which projects into the colon truncated and its opening widely flared. But the protecting ridge and the inclined plane behind this are still retained. The last form is one for use in pylorectomy In this one end is still more widely spread out, so as still more to protect the part which experience has shown is the most likely to leak—viz., that at the junction of the vertical with the circular line of suture in the stomach The method of use is obvious These bobbins have been very well made, and decalcified for me by Messrs Allen and Hanbury of Wigmore street, London

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

REFLEX MOVEMENT OF THE AURICLE OF THE EAR.

BY E DONALDSON, L.R.C P, L R C S IREL.,
SURGEON TO LONDONDERRY EYE, EAR, AND THROAT HOSPITAL.

A NUMBER of skin reflexes have been described, but I am not aware that amongst them a reflex movement of the auricle has been included My attention was drawn to this subject by the case of a man, aged 54 years, who came under observation on May 14th, 1902, on account of suppuration in the right middle ear with polypus The discharge commenced in the ear from some unknown cause when he was eight years of age and lasted until he was 25 He had no trouble from this time till the beginning of April, 1902, when the discharge again appeared and a good deal of pain followed. The polypus was removed by means of a snare. He was very deaf in this ear, not being able to hear either a loud voice close to the ear or a watch on contact. As part of the treatment I insufflated into the meatus some powdered boric acid through an ear speculum without holding the auricle At each puff the auricle was observed to move distinctly forwards to the extent of about one eighth of an inch, afterwards at different sittings I had a good number of opportunities of observing this reaction, and I found that I could produce it by blowing air from a small indiarubber bag into the auricle in the neighbourhood of the external meatus Usually the first puff gave the best result. The movement of the auricle would sometimes not occur after three or four puffs rapidly following one another At no sitting did I fail to get the reaction In making the observations I was careful to exclude voluntary movement, and movement that was only a part of a more general scalp movement. The patient was requested to prevent the reflex from taking place but he could not do so, and he was unable to produce the movement voluntarily He was quite conscious of the auricle moving to the air stimulus and said that he felt it "jumping" The left ear was normal and its auricle when blown into moved very slightly in a backward direction. Since I first noticed this reaction I have tried on several patients what movement of the auricle could be produced by blowing air from a small indiarubber bag into the auricle In many cases no movement was observed. I have found, however, that a slight upward, backward, or forward movement is not at all uncommon

It is remarkable that a puff of air is the stimulus capable of producing this reflex. It is well known that reflexes of different parts require their own peculiar stimuli—e.g, contraction of the iris is brought about by the stimulus of light, the plantar reflex by tickling, &c The appropriate stimulus in the reflex now under consideration is found to consist of puffs of air Is it possible to give any reason for this? Air rushing into the auricle and external meatus makes a noise and interferes with the hearing of other sounds and possibly may bring in with it foreign bodies Birds have no auricles and are not incommoded by the rushing of air into their external ears during their flight. It is said that in long-eared bats the auricle "is so constructed as to prevent air from rushing in while flying"[1] These considerations appear to me to go some way towards explaining why the auricle is more sensitive to puffs of air than to other stimuli

Londonderry

A CASE OF COMPOUND DISLOCATION OF THE HEAD OF THE HUMERUS INTO THE AXILLA

BY WALTER H. BROWN, F R.C S IREL, M R C S ENG

THE patient, a boy, 16 years of age, was admitted into Leeds General Infirmary with the head of his left humerus forced from its position and driven through the skin of the axilla so that it was fully exposed externally The accident was caused by his sleeve being caught in revolving machinery (a turning lathe) There was no fracture of the shaft of the humerus, but the great tuberosity had been torn off and so had all the muscular attachments together with the capsular ligament. Ether having been administered, the wound was enlarged and the dislocation was reduced, gauze drainage being used The radial pulse could not be felt at first but returned in 48 hours Sensation was not interfered with. Some slight suppuration of the edges of the wound followed, owing to skin infection. The limb was kept at rest by a cradle of Gooch splint and passive movements were commenced as soon as the wound healed. I have never met with a case like this before nor can I find any recorded in the English surgical treatises at my disposal but the condition is mentioned in a German work on fractures and dislocations, and the treatment there indicated is the same that I adopted. There is a good prospect of the patient recovering a useful limb From the rarity of the accident it deserves, I think, to be recorded.

---

[1] Quoted by Burnett in his Treatise on the Ear, p 29

The notes of the case were taken by the house surgeon, Mr R N Butterworth.

Leeds

AN UNUSUAL FRACTURE OF THE SUPERIOR MAXILLA.

By FRANKLIN COX, L.R.C.P LOND, M R.C S. ENG.

THE following case is of sufficient rarity to be interesting On July 16th, 1902, a man aged 38 years, was watching a game of quoits. Unfortunately for him he crossed the green between the two quoit beds just as a player was delivering his quoit weighing 9 lb and it struck him in the face, knocking him down. On examination the left superior maxilla was found to be fractured—the line of cleavage running along the roof of the mouth in the line of the intermaxillary suture, the two middle incisor teeth being almost out and the mucous membrane torn for one and a quarter inches in the line of fracture. Upwards it ran obliquely to a point about a quarter of an inch above and external to the left ala of the nose and then descended in a downward and outward direction to a point between the second upper bicuspid and the left first upper molar This could be made out by grasping the alveolar margin of the left superior maxilla with the forefinger and thumb when the V shaped piece of bone could be distinctly felt to move and when pulled gently forwards the broken margins could be distinctly felt. The skin over the fracture was not lacerated so much as one would have thought probable, but there was a deep wound laying the bone bare and extending from the middle line of the upper lip about a quarter of an inch below the nose upwards and outwards to the left for about one and a half inches. This wound has healed and the patient is doing well There was never any concussion of the brain.

Radstock Somersetshire

VACCINATION RETURNS.—At the meeting of the Exeter board of guardians held on August 12th it was reported that 431 births were registered during the last six months of 1901 and that of these children 304 had been successfully vaccinated, 11 were provided with exemption certificates 48 died unvaccinated 34 were provided with medical certificates of postponement, 17 had been removed from the district, and 17 were unaccounted for.—At the meeting of the Stonehouse (Devon) board of guardians held on August 14th it was reported that 238 births were registered during the year ended Dec 31st, 1901 and that of these children 200 were successfully vaccinated 18 died unvaccinated, five were provided with medical certificates of postponement, two were provided with exemption certificates 10 had been removed from the district, and three remained unvaccinated.—At the meeting of the Thornbury (Gloucestershire) district council held on August 1st it was reported that 299 births were registered during the six months ended Dec. 31st last, and that of these children 171 were successfully vaccinated and 15 were provided with exemption certificates.

BRISTOL ROYAL INFIRMARY

A CASE OF PYLORECTOMY

(Under the care of Mr ARTHUR W PRICHARD)

PYLORECTOMY is an operation of somewhat limited applicability for as it is chiefly performed for malignant disease of the pylorus, it is only suitable for those cases in which the disease is not extensive. The mortality from the operation has much lessened of recent years. In Professor Mayo Robson's tables,[1] containing all the recorded cases (572 in number) to that date the mortality was 30 per cent. but statistics limited to more recent cases give a much more favourable result Kocher in 57 cases had only five deaths—i.e. less than 9 per cent.

A domestic servant, aged 27 years was admitted into a medical ward at the Bristol Royal Infirmary on March 21st last complaining of indigestion She had had symptoms for nine years of pain in the stomach after eating and for the last three years there had been occasional vomiting with pain chiefly in the back. For three months before admission she had been much worse, vomiting two or three times a day and not always after food The vomiting was copious and gave her great relief She occasionally found a streak of blood but never in any quantity She thought that she had lost flesh considerably in the three months. The abdomen had been very tender and her nights disturbed. On admission she was a somewhat thin intelligent young woman with a decidedly tuberculous appearance but healthy in all respects except as regarded her digestive organs The appetite was bad and the tongue was very red and not coated Vomiting occurred frequently and often large quantities of fluid were brought up (once three and a half pints of clear brownish fluid) On examining the abdomen a hard tumour of about the size of a hen's egg was noticed in the middle line between the ensiform cartilage and the umbilicus which moved with respiration. A curved ridge could be traced on the surface of the abdomen passing up from the tumour to the costal margin There was a distinct depression below the ensiform cartilage 10 days after admission the patient was given to drink five half pints of weak boric lotion. The tumour moved to the right nearly under the eleventh rib the curved ridge descended to about half an inch above the umbilicus and there was dulness on percussion down to about two inches above the pubis. She subsequently vomited seven half pints and the tumour was again found in the middle line, the dulness below the umbilicus disappearing

Pyloric obstruction was diagnosed and efficient relief by medical means not being thought possible the patient was transferred to the surgical floor and as she was willing to submit to anything that would give her a chance of recovery Mr Prichard proposed to open the abdomen, thinking that a gastro-jejunostomy would probably be the operation best for her Accordingly on April 8th under ether he made an incision in the middle line above the umbilicus and at once came down upon the stomach, which was dilated A hard tumour of the size of a duck's egg was felt occupying the pylorus and adjacent end of the stomach It was moveable and it was possible to lift it up out of the abdominal wound without much stretching There were large glands in the greater and lesser omentum. An opening was made in the stomach well free of the growth and it was felt that the pylorus was narrowed and very hard and would not admit the finger It was then decided to remove the tumour instead of doing a gastro-jejunostomy The duodenum was clamped between two pairs of Swain's clamps well beyond the growth and the bowel was divided between them. The divided pylorus was pulled over to the left and first the greater and then the lesser omentum were ligatured off in sections up to the point where the stomach was free from disease This seemed to be about a quarter of the length of the stomach from the pyloric end A Smith's clamp was then put across the stomach about its centre and the stomach was divided well to the cardiac side of the growth The width at the part divided was between three and four inches The cut edges of the stomach were sutured together, beginning from above, sewing the mucous coat with un interrupted suture first and then the muscular and peritoneal coats afterwards Having dealt with the upper two inches Mr Prichard began from below and sutured in the same way the lower inch, this left an aperture of about one inch in diameter to correspond in size to the cut end of the duodenum This cut end of the duodenum was then brought in contact with the opening left in the stomach and by a continuous stitch the peritoneal coats of each were united posteriorly A continuous stitch was then taken the whole way round, dealing with the mucous membrane only, commencing at the back part. This stitch brought the mucous membrane of the duodenum in continuity with that of the stomach all round The peritoneal coats at the top and bottom and in front were then sewn together, the stitch being continuous with that which had been put in the peritoneal coat behind Many vessels had to be tied from time to time in the wall of the stomach and bowel and elsewhere The parietal incision was closed in the usual way with silkworm gut All the other sutures were of silk.

---

[1] THE LANCET March 24th 1900 p [illegible]

The patient became a good deal collapsed about the middle of the operation, which lasted two hours, and two pints of saline solution were injected into a vein in the arm by Dr E H E. Stack with much benefit On getting back to bed a rectal injection of one ounce of brandy in five ounces of water was given About two hours after the operation fluids were commenced by the mouth (one drachm of brandy in half an ounce of water every hour, and one drachm of Carnrick's liquid peptonoids in half an ounce of water every four hours) Nutrient enemata of brandy, bovinine, the yelk of an egg, and peptonised milk every four hours were given, and a hypodermic injection of a quarter of a grain of morphia at night She had a comfortable night and retained all the nourishment given by the mouth and rectum. She passed urine and flatus, there was no vomiting, and the pulse was fairly good (100) On April 10th (two days after the operation) the nourishment by the mouth was increased, amounting to one ounce of fluid every hour, water gruel and albumin water being added On the next day 30 ounces were given by the mouth in 24 hours, the bulk of the nutrient enemata was reduced, and the brandy was diminished She improved every day, raw meat juice and chicken broth being added. The wound was dressed on the fifth day and was satisfactory Bread crumbs were given in the chicken broth on the ninth day, and on the tenth day all the stitches were taken out, the wound being healed She had sweetbread for dinner on the fourteenth day and on the 28th chicken and bananas Except for one day when she was sick her convalescence was uninterrupted This upset seemed to be simply a bilious attack. She now says that she feels better than she has done for years

Remarks by Mr PRICHARD —As to the nature of the growth there is some little doubt The section was so white and hard that it presented all the characteristics of scirrhous carcinoma, moreover, the glands in the immediate neighbourhood were enlarged and hard and the mucous membrane was ulcerated over the growth But the microscope does not corroborate this It is not scirrhus or epithelioma. Is it simply inflammatory or fibrous thickening of a scar of a healed ulcer or is it tuberculous? The patient's appearance favours the last opinion, but nothing was found to prove it. In conclusion, I must say that I do not take the credit of the success of this case all to myself The patient was very well nursed and was of a very placid and hopeful spirit, but above all I have to thank Mr H. F Mole, our house surgeon not only for his ready help at the time of the operation, but for his unceasing care in the regulation of the dietary afterwards To him I believe the patient in no small measure owes her life.

HERTFORD INFIRMARY

A CASE OF SPINAL MENINGO-MYELOCELE, OPERATION IN AN INFANT AGED 13 DAYS, RECOVERY

(Under the care of Mr R. ODELL.)

IN cases that admit of it removal of the meningocele by operation is the most satisfactory method of treatment of spina bifida, for Morton's method, though very well suited for pre-antiseptic days, cannot be looked upon as a satisfactory method except for certain pure spinal meningoceles. The very youthful age of the patient in the case recorded below renders it especially noteworthy The commencement of sloughing of the skin made the operation imperative.

A female child was admitted into the Hertford Infirmary on May 17th, 1902, with a central swelling in the lower lumbar region of the spinal column, it was of the size of an egg, had existed since birth, and was gradually increasing in size. The skin over it was thin, bluish red, and was commencing to slough centrally It was non pulsatile, the base of the tumour was surrounded by a ring of bone There was fluctuation and pressure caused some diminution in bulk but did not affect the condition of the fontanelles There was some incontinence of urine and fæces; the anus was patulous and the mucous membrane was slightly protruded. There was no evident loss of power in the legs and no trophic changes were present. The weight of the infant on admission was seven and a half pounds At the operation the child was placed in the prone position, with the hips elevated and the head lowered No anæsthetic was given. An incision two and a half inches long was made somewhat to the left of the middle line - The cord was found adherent to the sac wall and was carefully dissected off and returned into the spinal canal. The flaps of the membranes were brought together over it and were sutured with fine silk The sloughing portion of the skin was removed and the remainder was brought together and joined by silk. A firm aseptic pad was used as a dressing. About an ounce of cerebro-spinal fluid was lost during the operation There was some collapse on the evening of the operation and two normal saline injections were made in the flank with satisfactory results The wound progressed favourably, the child gained one and a half pounds in weight during the two following weeks and two inches in circumference at the umbilicus, and the mother stated that there was increasing control over the sphincters On July 26th there was a perfectly sound cicatrix and no recurrence of the tumour had taken place

Reviews and Notices of Books.

Psychology, Normal and Morbid By CHARLES A. MERCIER, M B, M R.C P Lond, F R.C S. Eng London Swan Sonnenschein and Co Limited. 1901 Pp 518 + xiii. Price 15s

DR. MERCIER has produced a work which is notable equally for matter and for style. The master of a facile pen, he has prepared himself for the task which he has undertaken by wide and critical reading, with the result that his book presents both a theory which is his own and a synopsis (not the less intelligible and instructive for being informal) of the best work that has been done before his time Of his own work Dr. Mercier writes in his preface with conspicuous modesty that he has thought it better to publish the book "as it is, with all its faults," than to extend a delay in the course of preparation which threatened to be indefinite in duration Of the conscientious labour by which he has sought to harmonise the whole and to incorporate in the chapters first written the emendations and developments which occurred to his mind as the work progressed there are many indications, chief among which is, we may remark, the high degree of coherence which he has actually given to a very discursive work. Probably no writer who has set himself to work out an elaborate argument ever felt wholly satisfied with the whole result of his labour, the most have far less ground for such satisfaction than has our present author

The subject of which he treats is psychology in the older sense of the term—approached, that is to say from the subjective side. The morbid in the title is perhaps suggestive of the clinical aspect of mental disease, with which this work has very little to do. In fact, the morbid conditions which are treated here are regarded in the light of normal conditions working inharmoniously and no attempt is made to connect lesions with manifestations of mental alienation. The work is a serious effort to illustrate that most obscure of all regions of research in which one-half of the data are supplied by facts of consciousness and the other half by facts of observation. To correlate the one class of facts with the other involves the clearest as well as the deepest thinking and the thanks of all medical men are due to those few writers whom aptitude and education have fitted to extend the dominion of thought over this inhospitable region of philosophy To Dr. Mercier a notable rank among such writers is due, for he adds to the copious knowledge to which we have referred a power of close and accurate reasoning and a facility in the statement of abstract propositions which are hard to find in combination.

The nature of the subject and the dimensions of Dr Mercier's book make it impossible to review his work save in the most general way and in a general sense it is not necessary to add to what we have already written since such criticism as we should have to offer would not affect the estimate which the reader will have already formed of the unusual merit of this book. There is, however one point of sufficient importance, although not capital, to call for mention in this connexion. Dr Mercier in discussing the relations of ideas to one another builds largely upon the analogy of mathematics and in particular of the rule of three. The value of this analogy cannot be denied but we suspect that our author over-estimates it, and whatever may be thought of its merit as a guide through the intricacies of related thought we are clear that he relies too much upon it as a form of expression. Much that he writes is rendered more difficult without becoming the less obscure by being cast into the formula a b in the various and complicated forms in which this expression recurs *passim* throughout the work. *That is our single depreciatory* remark

Small pox How it is Spread and how it may be Prevented
By JAMES WALLACE, M.A. M.D Glasg London H. J Glaisher 1902. Pp. 69 Price 2s 6d. net.

IT is frequently remarked as a matter for regret that the valuable material contained in the report of the Royal Commission on Vaccination with its several appendices should be hidden away in more or less inaccessible blue books. Dr Wallace's work which is based on the inquiry which Dr T D Savill held on behalf of the Commission into the epidemic of small pox at Warrington in 1891—92, is therefore very welcome at the present time, when anything concerning small pox is of special interest. This inquiry was of especial value for several reasons. In the first place Warrington was in 1772—73, in pre-vaccination times, the scene of an outbreak of small pox the like of which has not been known since the introduction of vaccination. The opening chapter of Dr Wallace's book treats of that epidemic. At that date the mortality was 12 out of every 29 persons attacked, and 26 4 per 1000 persons living, as compared with 0 6 per 1000 in the vaccinated *population during* the epidemic of 1893 93 The causes origin, development, and decline of the epidemic in 1892-93 are then narrated. The brief outline of the beginning of this outbreak is extremely instructive proving the necessity of (1) early recognition of the disease by medical men and (2) ample accommodation in isolation hospitals. The relations of small pox and vaccination are next discussed and statistics are freely quoted demonstrating respectively (1) the power of vaccination to protect from small pox (2) its efficacy in modifying the disease and (3) the duration of the protective power of vaccination Under this last heading the statistics illustrate the variation both in the severity of the disease and in the case-mortality according to the age of the patient and their vaccinated condition. The following chapter naturally passes to the consideration of the influence of revaccination An interesting fact elicited by the Warrington inquiry was that the protection afforded by revaccination and that afforded by a previous attack of small pox respectively are in general terms almost equally efficient. Dr Wallace puts this somewhat strongly when he says that revaccination affords more protection against small pox than a previous attack of the disease does As regards the duration of the power of revaccination it is interesting to note that of all the revaccinated persons in Warrington not one of them contracted small pox who had *been revaccinated a shorter period than seven years* prior to the date when he contracted the disease. The influence of revaccination is further shown by the rapid diminution of the disease starting 14 days after revaccination had been extensively performed in the principal works" of the town. In view of the growing importance of this subject and inasmuch as there is strong evidence (as shown in Dr Savill's report) to prove that the protective power of infant vaccination is largely lost after the age of 10 or 12 years it would be well if Dr Wallace in his next edition were to take statistics also from other sources—from Germany, for instance, where not only vaccination but revaccination is compulsory and where rumour says that small pox is being stamped out in consequence. The closing chapters of the book discuss the diagnosis of small pox, the methods of procedure in preventing it spread and the effects of social and sanitary conditions on the disease Particular mention is made of the fact that the inquiry into the epidemic at Warrington conclusively proved that the spread of the disease, which at first sight seemed to be due to aerial convection could, if sufficient pains were taken in the investigation, be shown to be due in all cases to direct or mediate contagion. This is peculiarly interesting since another observer of the same epidemic had previously come to the opposite conclusion.

Dr Wallace's little book should be in the hands of every busy practitioner and every intelligent layman who desires facts as distinct from theories concerning small pox in a small compass concisely and clearly stated. It is well printed and bound and the chief points are rendered easy of reference by paragraph headings in conspicuous black type that readily catch the eye and remain in the memory It is by the issue of such books as these that that section of the public which approaches these questions with an unprejudiced mind can be enlightened on so many points upon which enlightenment is needed.

Public Health and Preventive Medicine By C J LEWIS M D D Sc. (Public Health) Edin and ANDREW BALFOUR, M D B.Sc. (Public Health) Edin D P H Camb. Edinburgh William Green and Sons. 1901 Royal 8vo. Pp 6.8.

THIS is an ambitious and very comprehensive work which has, in our view fallen a little short of the ideal which the authors set before themselves It is nevertheless a work of a high order of merit and worthy of attention But the ground which the authors have endeavoured to traverse cannot well be properly covered even in a volume of this size and the concentration which has more particularly in certain directions, been attempted has, we fear, deprived some of the subjects of much of the interest which naturally attaches to them. Although this is our general impression there is much to commend in the work which, by the way, contains numerous and excellent plates, both coloured and plain.

The arrangement of the work is original. There are five sections. The first 124 pages deal with Medicine in Relation to Public Health, and the remaining four sections are devoted successively to General Sanitation, Sanitary Engineering and Building Construction, Vital Statistics, and Sanitary Administration and Sanitary Law. It is in the treatment of the first section that the authors have taken what is practically a new departure. In the description of each of the communicable diseases its bacteriology receives prominent and fairly full consideration, which has tended to accentuate the difficulty of dealing adequately with all the subjects which the authors have decided to embrace in their treatise. It has, too, led to a lamentable curtailment of what may be called the epidemiological aspects of the several diseases, and it is this which is, in our opinion, the weakest side of the work. This is more particularly the case seeing that the book is written, according to the authors' preface, primarily for those about to take the diploma of public health. It is essential in a text-book to maintain, as far as possible, the interest of the student and to furnish him with facts which he will easily retain in his memory. The many outbreaks of enteric fever which have been so well investigated are read even with avidity by the student, but in the book before us there is but scanty reference to any of them, and none are dwelt upon in at all a readable fashion. A similar remark applies to many of the other diseases treated of. For instance, small pox, concerning which every student of public health should be well posted, is disposed of in under two pages, and in the case of plague the bubonic type is dwelt upon fairly fully, but the pneumonic and septic types are passed over lightly. But for this relegation of the epidemiological aspects of the several diseases to a relative obscurity the matter is excellent, and the coloured plates of bacteria and parasites are some of the best that we have seen. If the student can master all the details he need have no fear of his examiner, but the tax on his attention and memory will be a severe one.

The diseases of occupation and alimentation are very concisely dealt with, although the matter takes too much the form of a notebook—an elaborate and well arranged notebook be it understood—to form easy reading. The section on General Sanitation comprises meteorology, climate, air, soil, disinfection, preventive inoculation, school hygiene, &c., and much of it is very good. But vaccination ought to have been more fully dealt with and it seems a little out of date in these days of general vaccination with glycerinated calf lymph to point out that "arm to-arm vaccination requires great care in the selection of vaccinifers." Only a few lines are devoted to preventive inoculation other than vaccination. The section on Sanitary Engineering and Building Construction embraces a somewhat heterogeneous collection of subjects, such as ventilation, warming, water supply and sewage disposal, and in connexion with this latter subject less space might well have been devoted to chemical methods and more to biological. The section on Vital Statistics is well written, although we are rather surprised to find the seasonal prevalence of infectious diseases under this heading. The principles of Sanitary Administration are admirably described and infinite pains have been taken to make the exposition of sanitary law complete and helpful. To this latter subject a large portion of the volume has been devoted and we cannot help thinking that the authors would have been well advised had they expanded the section on Medicine and relegated Sanitary Law to another volume. The fact is, a system of three volumes might well have been devoted to the subjects which the authors have attempted to compress into one volume.

This book, although, in our opinion, not perfectly fitted for students of public health, will be most helpful to medical officers of health and others who, being familiar with the general principles of the science, are anxious to refresh their memories and to bring their knowledge up to date. In this sense we wish the volume the success that it thoroughly deserves.

LIBRARY TABLE.

Epitome of the Synthetic Philosophy of Herbert Spencer. By F. Howard Collins. With a Preface by Herbert Spencer. Fifth edition. London: Williams and Norgate. 1901. Pp. 692. Price 21*s.*—This work, which is well known already, as the appearance of a fifth edition would alone suffice to prove, has been enlarged for the purpose of the present publication by the inclusion in the work of references to Mr. Spencer's now revised editions of the "Principles of Biology" and "First Principles." It serves the full purpose of a synopsis, such as it purports to be, of Mr. Spencer's system of philosophy and has been produced chiefly by the process of cutting off illustrative matter. In this way the voluminous works of the principal author have been collected into the manageable compass of this volume and made accessible to readers to whom time is wanting for the more extended reading necessary to make acquaintance with the originals. Such digesting work in reference to original matter of the character of Mr. Spencer's philosophy is of high value, and performed as it has been performed by Mr. Collins it fully merits the public appreciation which it has unequivocally received.

The Health Officer's Pocket Book. By E. F. Willoughby, M.D. Lond. Second edition, revised and enlarged. London: Crosby Lockwood and Son. 1902. Price 10*s.* 6*d.* net.—This is the second edition of an eminently scientific little volume of 424 pages and of such dimensions (6½ × 4 × 1⅛ inches) that, unlike many so-called pocket-books, it may conveniently be carried about. The book is already well known to medical officers of health, as the first edition appeared in 1892 and it is therefore unnecessary to dwell in detail upon its contents. As Dr. Willoughby states in the preface to the first edition, the medical officer of health and the sanitary inspector are frequently called upon to give impromptu advice when they are out of reach of the books kept in the public offices, and it is to them that this collection of 'facts, figures, and formulæ" will strongly appeal. The data are collected with a due regard to the frailty of the human memory, and not only will many of them be found useful when the medical officer of health is away from home, but the tables of logarithms and the mathematical data generally will prove helpful in the compilation of annual reports and in the calculation of dietaries. In a word, the volume is well fitted both for a pocket- and a desk-book. In the second edition much of the volume has been rewritten and the whole book has been revised and brought up to date. Part I. treats of practical hygiene, and Part II. deals concisely with sanitary law, embracing in abbreviated form the Public Health (London) Act, 1891, and the Public Health Act, 1872, together with notes on these two Acts. There is also a "comparative view of health Acts" in which the corresponding sections of the two principal Acts are arranged in parallel columns. There is, moreover, a capital summary of other Acts relating to the public health, including the Factory and Workshops Act, 1901. The appendices embrace useful information and there is a good index. In Appendix B it would have been better had the new statistical tables of the Local Government Board been introduced rather than that the old Tables A and B should have been retained. But we can cordially commend the volume as one which will be found most useful to the officers of sanitary authorities.

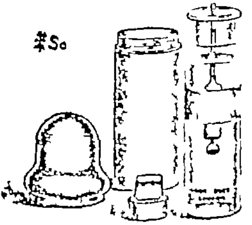
Health, Speech, and Song: a Practical Guide to Voice Production. By JUTTA BELL-RANSKE. With 18 Illustrations. London: Swan Sonnenschein and Co., Limited; New York: E. P. Dutton and Co. 1902. Pp. 159. Price 4s. 6d.—Mrs. Bell Ranske attacks the problem of so-called voice production in a methodical way, dividing the analysis of the component parts into the vocal organ, the motor elements or breath, and the resonator. The vocal organ is considered as an element. This is a little difficult to grasp and the wording of this chapter leads us to the opinion that the author herself found it as difficult of expression. We must own that it fails to convey any lucid impression to us. Here is one sentence which shows the knowledge on which some of the statements are based:

The vocal cords lie stretched across the larynx, fastened in front where the shoulders meet in their angle, and at the back to two small pyramidal muscles (the arytenoidei) which are fixed on the upper ring of the windpipe. The false cords are said to act in contrary motion with the true, which is a phrase also hard to comprehend. And when we are gravely informed that the only muscle that remains to be mentioned is the epiglottis it is obvious that knowledge is necessary in order to describe the anatomy of the vocal organs. The various ideas of the so-termed schools are described in detail as the "Larynx School," the "Pharynx School," and the "Resonance School." Undoubtedly Mrs. Bell Ranske has a keen appreciation of the great necessity of efficient natural respiration and of the great importance of chest development, while the importance attached to a proper carriage and deportment generally is extremely practical. But in the advice to singers Mrs. Bell Ranske appears to be unable to express intelligibly what she wishes to say.

New Inventions

A URINE SPECIMEN BOTTLE.

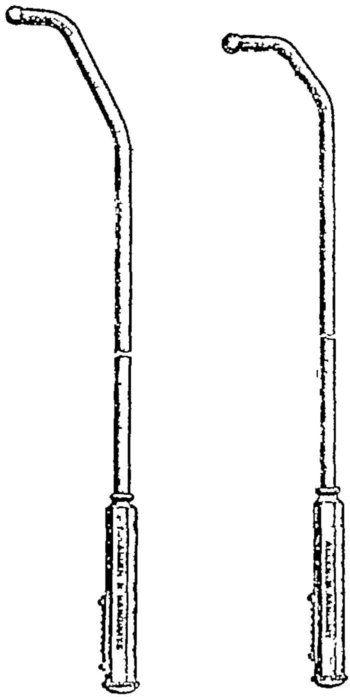
MOST practitioners must have suffered at one time or another from leakage from bottles containing specimens of urine which they have been taking home to test, and many must have found strange and unwonted substances in specimens sent them in bottles provided by their patients owing to the bottles having contained medicine and being used without being efficiently washed. To obviate these *contretemps* I have had some urine bottles made for me by Messrs. Down Bros., one or two of which I carry with me in my bag on my rounds, and use for taking home any specimen of urine I may wish to test. They are two-ounce stoppered bottles with a wide mouth, the mouth being wide enough to admit an ordinary urinometer. Each bottle is provided with a place for writing the name of the patient and the date, and they are inclosed in boxwood cases so that there is no danger of any leakage. I find them much appreciated by patients, especially those whose urine has to be examined at regular intervals, and they have been a very great convenience in my own work.



Ryde. H. CARTER THORP, M.A., M.B., B.C. Cantab.

TWO USEFUL BLADDER SOUNDS.

I CANNOT find that the adaptation of the useful bi-coudée catheter bend has been applied to sounds and this seems a little remarkable. These sounds are, of course, intended chiefly for prostatic cases, although not exclusively. Every one knows the difficulty of using and the deficiencies of ordinary sounds in many cases. The beaks of these sounds are at right angles to the shafts and this, together with their shape otherwise, renders them capable of extending over, and searching behind, the enlarged lobes. The chief advantage, however, is the ease with which I find them to pass. Both sounds are flattened at the convexity and flattened and narrowed at their beaks from side to side, these improvements rendering them easy to pass over enlarged middle and between approximated, lateral prostatic lobes. The sounds are made by Messrs. Allen and Hanburys, copies of some I made myself a considerable time ago.



Finsbury-pavement, E.C. JAMES MACMUNN.

PLYMOUTH BOROUGH ASYLUM.—At the meeting of the Plymouth borough council held on August 11th tenders were accepted for the extension of the Plymouth Borough Asylum at a cost of £35,967.

CRUELTY TO LIONS.—The Royal Society for the Prevention of Cruelty to Animals recently obtained at Dorchester the first conviction under the Wild Animals in Captivity Act, 1900, in regard to lions. The defendants were the proprietors of a travelling menagerie and were charged with causing cruelty to a lion and lioness by insufficiently feeding them. One of the defendants admitted that they had had a difficulty in getting food for the lions but he denied that they suffered in consequence. His brother gave a performance as usual, putting his head into the mouth of one of the lions, and if it had been starving it would have attacked him. Each of the defendants was fined £1.

THE LANCET.

LONDON SATURDAY, AUGUST 23, 1902

ne Surgery of Chronic Dyspepsia

IN the present number of THE LANCET appear two papers which serve to show very clearly the immense benefit which surgery may afford in certain cases of chronic dyspepsia where the symptoms make life unbearable. One paper is by Dr T KENNEDY DALZIEL, professor of surgery in Anderson's College, Glasgow, on 30 Cases of Gastro-enterostomy for Non malignant Affections of the Stomach, and the other is by Mr A. E BARKER, surgeon to University College Hospital, on Some Cases of Operation for Chronic Non malignant Disease of the Stomach

Chronic dyspepsia has from time immemorial been one of the greatest opprobria of medicine. Judicious medicinal and dietetic treatment relieves many of the cases, but there are still many remaining in which all ordinary treatment fails to do any permanent good. The immediate danger to life is small—for here we are not speaking of malignant disease—but existence is a burden Unless the greatest care is devoted to the diet discomfort and pain will torment the patient for hours after a meal and often relief will only be obtained when the stomach rejects its contents. Sometimes the vomiting may be profuse, many pints being brought up The food, whether ejected or retained, fails to nourish Emaciation, often extreme, naturally follows The sufferer, worn out with pain and weakened by lack of food, falls at length into such a state that death itself comes as a relief Even when the symptoms are not so extreme they are sufficient to interfere with ordinary life. The patient is able to devote himself to only a very limited extent to his work He cannot forget his dyspepsia, his mind is centred in his stomach, his diet, his beverages, his symptoms occupy his whole attention and he has none to devote to the ordinary concerns of life Every medical man can testify to the correctness of this picture. Fortunately, such extreme cases are not very common, but instances of a milder type are often met with, and everyone must acknowledge how little relief is to be expected from drugs There are doubtless some of these cases of disease which are functional in origin and in which the most minute examination of the stomach and abdominal viscera after death cannot reveal any lesion, but these form the exception, for in the majority of cases a necropsy will show some definite structural change to which may reasonably be attributed all the symptoms For many years a connexion between these chronic dyspepsias and some definite organic disease of the stomach was hardly suspected. They were not cases likely to be detained in hospitals for any length of time and therefore would but rarely come to a necropsy, for post mortem examinations are very exceptional outside hospitals But it came gradually to be recognised that in many cases some definite structural change could be found, and now it may confidently be laid down that in the vast majority of cases of severe chronic dyspepsia the disease is not merely functional but has an organic basis. The conditions discovered on examination are very various, but it is remarkable that a large proportion of them result from the healing of simple gastric ulcers As the ulcer heals it contracts and so may lead to constriction of the pylorus, if it be situated near that orifice. On this constriction follows the whole train of symptoms associated with dilatation of the stomach Should the ulcer be placed more nearly in the centre of the viscus its cicatrisation may lead to a mesial narrowing so as to produce the "hour glass" stomach. Again, as a gastric ulcer extends in depth it may form adhesions to surrounding viscera. When the ulcer has healed these adhesions remain and may produce tractions on the stomach itself or on neighbouring organs, or obstruction of the duodenum. These are the chief lesions discoverable, but many variations and combinations of them may be found producing great variety in the details of the symptoms In some of the cases described in Dr DALZIEL'S paper adhesions were the result of peritonitis originating from old tuberculous glands behind the pylorus, and these adhesions prevented the emptying of the stomach. Sometimes, again, the gastric muscular movements may be interfered with by firm broad adhesions

For all these cases medicine is of little avail A carefully restricted diet and the administration of gastric sedatives and antiseptics may lead to some remission of the symptoms or even to great improvement The relief is, however, but temporary and a return of all the discomfort and pain follows at once on a return to ordinary diet In cases where there is gastric dilatation great relief is often experienced from washing out the stomach regularly, and this "lavage," as it is called, is by no means so unpleasant to the patient as might be expected—in fact, it is frequently asked for, as the patient recognises the good it does Lavage is useful, too, even when no dilatation of the stomach is present, for it removes from that organ the undigested decomposing residue of the last meal. Lavage, however, is at the best but a palliative, and operative interference is needed to produce permanent results. Of all the operative methods of treatment for these cases there is one the results of which are more satisfactory than those of any other This is gastro-enterostomy, the lateral attachment of the upper part of the jejunum to the stomach Its mode of action is two-fold. In the first place it enables the stomach to empty itself completely and easily, so that accumulation and decomposition of the contents are no longer possible. This is the way in which so much benefit is obtained from it in cases of non malignant pyloric stenosis There is yet another method by which gastro-enterostomy does good it affords physiological rest to the stomach, and this is of vital importance in cases where that organ has been incessantly irritated for months or years. The operation is best preceded by lavage of the stomach for several days to render it as free from micro-organisms as possible

What are the results? For on the excellence of the results depends the justifiability of the whole operation First as to the mortality In capable hands this is exceedingly low—probably not over 3 per cent. Secondly, as to the effect on the symptoms. The relief in most cases is immediate, great and permanent. The emaciation rapidly disappears, the dyspepsia vanishes, and ordinary food can be taken with impunity. Of course, so completely successful a result is not obtained in every case but the benefit is nearly always striking. Care must be used in the selection of cases suitable for operation, for only harm can result from indiscriminate laparotomy. The symptoms must be of sufficient severity and duration to justify having recourse to an operation which, however carefully and intelligently performed, cannot be free from risk. But in suitable cases the results are worthy of an age of surgical progress, as will be at once obvious from reading the two contributions to our columns which have prompted these words.

◆

Hospital Abuse.

AT the recent annual meeting of the British Medical Association Dr. ALFRED COX of Gateshead and Mr. J. T. J. MORRISON of Birmingham both called attention to the fact that in some towns it was the working-class vote that would predominate in the management of hospitals. There is no reason why working men should not contribute their share to the public charities, but that is not the way in which they view their subscriptions to hospitals. They have been accustomed to subscribe to friendly societies, to medical aid clubs, to slate clubs, to trades unions, and other such institutions. In each and every case the money they give comes back to them in hard cash or in services rendered, and further they generally have a vote in the management of the funds which they thus raise. Consequently they naturally imagine that if they support the hospitals they should not only have a vote in the management of the hospitals but that the hospitals are bound to render them services in exchange for the money subscribed. The workmen do not give to the hospitals as an act of charity but they pay so as to wipe out the charitable aspect of the institution. They propose to purchase, as it were, a right of entry to the hospital and a right to be treated not as the recipients of charity, but as provident people who have insured themselves against the risks of sickness or accidents. This is the feeling that undoubtedly prevails though it has not yet been formally inscribed in any document, agreement, or covenant.

Our Special Commissioner in the series of articles on Hospital Abuse gave a very full account some five years ago of the growth and development of the Birmingham Hospital Saturday Fund.[1] At that time it was estimated that 75 per cent. of the workmen of Birmingham subscribed to this Fund and they raised about £15,000 in the year. Now we are told that they subscribe £18,000 and therefore, perhaps more than three-fourths of the working classes are at present involved in the movement. As most of the money is raised by means of penny weekly subscriptions this would mean that there are some 83,000 subscribers. The total population of Birmingham, including women and children, is set down at 478,113, therefore it is safe to say that the vast majority of the working men are subscribers. Besides, they also subscribe several thousands of pounds direct to various hospitals obtaining tickets in exchange, and this is done over and above their subscriptions to the Hospital Saturday Fund. Taking the total annual revenue of the hospitals in Birmingham as about £41,000, if the working-classes were to withdraw their support the hospitals would at once be bankrupt. They know this and they feel that they are masters of the situation. This is all the more the case as with the increase of working-class support there has been a decrease in the amount of subscriptions received from the wealthier classes. Though less accentuated than at Birmingham, the same state of affairs is noted in other towns. Our Commissioner pointed out that out of an income from all sources of £10,921 received by the Leicester Infirmary the donations from the working-classes amounted to £3187.[2] At Leeds the workmen's subscriptions represented about one-fourth of the total income of the hospitals,[3] and now Dr. ALFRED COX states that in the North of England, notably at Gateshead, the workmen subscribe such large sums that not only do they conceive that they are paying for the treatment they receive but maintain that they have a right to govern the hospitals, the move being directly towards the municipal ownership of the institutions. In dealing with Birmingham our Commissioner pointed out that if the majority voluntarily taxed themselves they would soon demand that the minority should be coerced into paying their share of the required contributions. Thus the subscription would be converted into a tax and the private funds would be replaced by the municipal administrations which would manage the general hospitals as they already manage the hospitals for the treatment of the insane and for the isolation of infectious cases. This represents, of course, the extreme outcome of the present situation, but unless the hospitals should revert to the old system and take measures to obtain the bulk of their financial support *from the* wealthy and well-to-do classes it is the obvious issue.

The question has now entered into a vicious circle and every step taken only aggravates the difficulty. The more the workmen give the less do the other classes give. The more the workmen give the more general does the abuse of hospitals become, because giving such large sums in the aggregate they do not see that they are not contributing their just quota and are not really paying for service rendered. The more hospital abuse prevails the more disinclined will the well-to-do classes be to subscribe. Practitioners in the poorer districts of the large towns say that it does not pay them to buy surgical instruments for the *minor* as well as the more serious surgical cases now all gravitate towards the hospitals. Why should, for example, the parents, relations, or private friends of young practitioners subscribe to hospitals when these institutions are so palpably injuring the prospects of those in whom they take an interest? The knowledge is spread that the money of the charitable subscribers is being misapplied and the amount given therefore decreases. But this only leads the managers of hospitals to rely more and more on the working-classes and therefore they refrain from making inquiries when cases of abuse are signalised lest subsidies that have now become valuable should be withdrawn. For the Coventry Hospital the working classes gave £300 more in 1896 than in 1895, the other classes £123 less, the country parishes £10 18s. less, and the legacies were £70 less. The working men subscribed more than a third of the total receipts and insisted on having 45 working men governors appointed.[4] It is true that the agitation against hospital abuse has led to a few reforms here and there but such sporadic attempts will not meet the case. Also, even if they are successful they will assuredly reduce the amount subscribed by the working-men who thoroughly believe in their legal right, having paid their pence, to hospital treatment in all circumstances. They do not see that the medical work of the hospitals is done by medical men gratuitously because they are charitable institutions, and for no other reason whatever. At paying hospitals the fees to be paid are not the pennies which the patients feel like giving but the sums which are considered to represent the value of the services rendered. All honour to the working classes for giving as much as they can, but they must not give a penny and expect to obtain a pound in return as their inalienable right. This is a view which ought to be brought strongly before the public.

A Ministry of Public Health

IN the development of any new social force there comes a time when the channel which in the first instance afforded a sufficient outlet for its energy is no longer adequate, and if the outlet be not enlarged by those who are in a position to recognise its insufficiency events resembling volcanic eruptions are likely to take place. At the present moment there are many thoughtful and moderate men, having at heart the advancement of preventive science and the improvement of the sanitary environment under which a large portion of the community lives and works, who feel that the hour is at hand when the channel by which the public health service of this country found expression a quarter of a century ago might usefully be expanded—that, indeed, such expansion is necessary and has been shown to be necessary by circumstances of an eruptive nature.

Those who chance to have read the remarks of the famous Dr. W. FARR in the supplement to the thirty-fifth annual report of the Registrar-General, and who will take the trouble to contrast the existing administrative machinery with that which obtained in 1875, will see that the programme therein outlined by the great statistician has in the interval been largely realised. We have now a medical officer of health for every sanitary area and in this sense Dr. FARR'S ideal is attained, but only a small proportion of such officers are as well qualified as could be wished, either in a scientific or administrative sense, for the duties which the State expects them to perform, and the pay is frequently altogether ludicrous. But, this notwithstanding, the strides made in sanitary science in every conceivable direction have been those of a giant, and it is not too much to say that the spirit of preventive medicine now permeates every branch of the public service and is an enormous force making towards the more wholesome living of all classes. But while this is so there has not been in the public health world that gathering together of the loose ends of work, or that concentration of the available energy, which is essential if the potential forces are to be employed with the greatest efficiency. The expansion and welding together of the empire and the general spread of scientific knowledge have outstripped in this country our machinery for the maintenance of public health. There is, it is true, an excellent nucleus for a broad and vigorous public health service for England and Wales, but, viewed in relation to the needs of the empire, the nucleus must have larger possibilities if it is to serve as an adequate centre for future development. The Medical Department of the Local Government Board is, in effect, the central health department of the country, but the Medical Department finds Parliamentary and public expression only through that somewhat heterogeneous collection of sub-departments known as the Local Government Board, of which it is but a branch. If we apply the usually accepted standard of value, that of status and pecuniary emolument, it must, we fear, be inferred that the Board does not set an over-high value upon its public health work. This is the more regrettable because, although there is perhaps scope for initiative on the part of the Board in matters appertaining to preventive medicine, the inquiries conducted by the inspectors of the Medical Department are conducted with a thoroughness and impartiality which merit and possess the confidence of the country. Were this department expanded and were the Board clothed by Parliament with greater powers for initiative action but little fault could be found with the nucleus of the Public Health Service. But the developments of recent years require, we think, that preventive medicine should bulk more largely in the aggregate of the Board's work and that the President for the time being of that Board should feel that he alone is responsible to Parliament and to the country for the health of the people. And this brings us to a question which is now frequently asked and which will soon be ripe for answer. Is not a further expansion desirable? Ought there not to be a Ministry of Public Health? It would seem reasonable that the public health duties, which are at the present time scattered over several Government offices, should be focussed in one department and that all matters affecting the health of the empire should, in so far as the central health authority is concerned, be dealt with in one department. Such an office should be the public health and statistical bureau of the empire, where uniformity in statistical methods and the nomenclature of disease should be arranged and where the public health material should be digested and turned to the best account. This is, we are fully aware, a somewhat ambitious scheme, but the aspirations of the empire are in no direction characterised by undue humility, and expansion in the furtherance of knowledge and the improvement of the public health are surely among the elementary duties which devolve upon us in consequence of our greatness.

Those who are opposed to the creation of what we have spoken of as a Ministry of Public Health base their very reasonable objection upon the belief that it is better for the cause of public health that the functions relating thereto should be exercised by a large department having a Minister of Cabinet rank as its mouthpiece than by a small office having no such advantage. We cordially agree with this, but it seems to us that a department having for its work the programme which we have here delineated might well have a Cabinet Minister at its head. This question of the formation of a Ministry of Public Health is likely to receive the attention at an early date of one or more societies concerned with the administrative side of preventive medicine, and it is for this reason that we set forth certain points for consideration There is no doubt that the public health service of the country cannot cope with the demands laid upon it by modern scientific knowledge a position which is bound to get worse. Sooner or later a big piece of constructive work will have to be done and the right man should be found to do it It would be worse than useless were the matter to be taken up by persons open to the charge of personal aggrandisement, while only those who understand public health questions, their difficulty delicacy and importance can realize that our present condition is not perfect. But the moment is opportune in many ways for the consideration of the whole matter The blessing of peace has been given to us while the lessons of the war point straight to the necessity of an efficient and up-to-date public health service. It would be idle to suggest that so radical and immediate a change as the formation of a Ministry of Public Health should be made with a member of the Government of Cabinet rank at its head. We do not expect such an innovation but we do expect that the new Government, doubtless starting with keenness on its work, should give the question of the public health of the country its best attention. And we believe that the most practical way of displaying knowledge of the present position and of the future to be provided for would be to consider seriously the formation of a bureau of public health

Annotations.

"Ne quid nimis."

TUBE RAILWAYS

WE publish in another column an article upon tube railways which we commend to the notice of our readers. The limitations of the article are definite, for we make little attempt to go outside our province and to deal with the construction of tube railways while our remarks on engineering problems of every kind are conspicuously absent. We have simply considered the tube railways now in construction in London and in great probability shortly to be constructed in most overcrowded capitals as a departure in social life which must have many more or less medical bearings. It is possible that some of our readers will in the near future be asked by their patients such questions as the following Are the tube railways safe from accident—as safe, that is as any railway can ever be made? Supposing the precautions taken to be adequate are the proper means provided for minimising disaster? Are the tubes properly ventilated? Will the vibration caused by the trains be so great as to constitute serious annoyance to the inmates of houses on the route? Questions like these cannot be positively answered for it must be remembered that many points will not be made clear until the trains are actually running All that comment and criticism can do at the present moment is to urge the necessity that rigid precautions should be observed to obviate the tubes becoming a source of danger or annoyance, and that advantage should be taken of past unfortunate experiences. There can be no doubt, we think, that in London at any rate some such development in passenger traffic as we are now witnessing is urgently called for The schemes for the construction of deep-level railways now on paper or receiving Parliamentary sanction or actually nearing constructive completion demand we think the general approval if not the admiration in detail of all who live in, or work in, or are interested in the welfare and business position of London and this latter section may be taken without exaggeration to imply all the citizens of our empire and all the trading classes of the world. The danger to health and life and limb in our overcrowded metropolis with its terribly congested traffic are very real and are increasing by leaps and bounds It has become necessary that means should be provided whereby persons living at a distance from the business centre of the world can reach that centre at the expense of the minimum of time and trouble. Yet it is obvious that the easier the passage is made from the circumference to the centre the more congested the centre will become unless the increased traffic has new routes made for it. Such routes can only be placed above or below the existing routes, and it is well known that overhead railways are subject to the gravest disadvantages. Of underground railways two are possible the shallow and the deep. There is much to be said for the shallow railways and the London County Council is known to favour them, but the difficulty of construction is very great, the inconvenience caused during the work is incalculable and the expense is proportionately high This brings us to deep railways as the preferable solution for a problem that exists and grows daily in London at any rate, harder to answer Against deep railways it has been urged that their ventilation is faulty and that the damage that they do to structures upon their route by altering the drainage and formation of the soil cannot be estimated. We think that this is a pessimistic view based upon conditions which experience will not allow to recur The ventilation of the new tube railways is to be much more thorough than any previous scheme has provided for and the promoters of one and all the lines are awake to the gravity of asking the public to pass long spells of time in grossly vitiated atmosphere. There is evidence that the precautions that are to be taken in the new tube railways for doing away with vibration are also very sound and thorough while there seems no reason to suppose that any important settlements will take place if the tubes are constructed entirely in the deep-lying clay Of course the gravel bed above that clay must be pierced at the stations for the admission of passengers but every care known to the engineer having been taken to obliterate the space between the gravel and those shafts the wholesale injury to buildings on the route which has been so generally anticipated ought not to occur It will not occur unless some of the most experienced engineers in the country are wofully out in their calculation On the whole we think that we are in a position to assure our readers that the vast network of tube railways soon to be crossing and recrossing each other in the clay below London will not subject the public health to the strain that has been suggested, while the improved facilities for travelling ought to lessen the overcrowding which is now such a terrible source of disease in many quarters of the metropolis

COUNTY COUNCILS AND CONSUMPTION

THE attention paid by county councils to the treatment of consumption is a hopeful sign Both the Lancashire and the

Cheshire councils are moving in the matter At the meeting of the former on August 7th Sir John Hibbert moved the adoption of the report of the special committee appointed to consider the best method of appropriating the sum of £10,000 voted out of the county fund to commemorate the King's coronation. The committee unanimously recommended that it should be devoted to the establishment of an institution for the treatment of cases of consumption arising in the administrative county Sir William Houldsworth, while agreeing, doubted the possibility of doing much with so small a sum, and suggested that it might be possible to come to some arrangement with the hospital which Mr Crossley is providing for Manchester and Salford in Delamere Forest. After some discussion Sir John Hibbert agreed that the matter should be postponed At the meeting of the Cheshire county council held on the same date Mr W Hodgson drew attention to the same subject and spoke of the "magnificent sanatorium in Delamere Forest" provided by the munificence of Mr Crossley He thought, however, that the Cheshire council might be able "to do a sufficient thing, probably at somewhat less cost, and spreading the cost over the whole county it would not be much for each authority" The public health committee of the council had thought that nothing could be done unless notification were compulsory, but on inquiry at the Local Government Board this was found to be an error The report of the committee to the effect that it was desirable for a sanatorium or sanatoriums to be established in the county was approved and it was agreed to send it to the local authorities together with the gist of the letter from the Local Government Board. With regard to Sir William Houldsworth's suggestion as to negotiating with the Delamere hospital it should be remembered that the Liverpool sanatorium is not much more than half a mile away and it does not seem desirable to bring too many of these institutions to the same locality Lancashire has many most salubrious sites quite as good as that of Delamere

SOME ADVANTAGES OF A RAINY SEASON

The summer of 1902 so far has been horrible It is the more unfortunate that it has been so as it was the year set apart for great national rejoicings To the majority it may be a source of satisfaction that grumbling is justifiable, and he who can cast about for and find a few redeeming features in regard to the excessively unpropitious weather which we are experiencing proves the possession of virtuous content. One fact may prove a solatium, and that is that it was impossible to run away from the weather by leaving England, for equally bad, and in some cases a good deal worse, weather has been the rule apparently over the whole world Certainly in many places where highly favourable weather so often obtains the conditions have been worse than those prevailing in the British Isles Italy, for example, has been visited with snowstorms and a cold season has been recorded which for its bitterness appears to be without precedent. Other countries reported to be commonly blessed with sunny skies have shared the same experience In this fact, perhaps, may lie a crumb of consolation, but it is small. Greater consolation surely may be found in the fact that in London, at any rate, and in many other big manufacturing towns the almost torrential rain which has been experienced during the last few days has provided us with a wonderfully clean and clear air The freshness and transparency of the air of London are well known effects of a sharp rainstorm. The continual bombardment of the air by millions of pure water drops exerts a mechanical effect, a physical effect, and a chemical effect, all of which play a part in a hygienic purpose. There is the mechanical effect of removing suspended particles—dirt, dust, smoke, micro organisms—and carrying them to earth, there is the physical effect of a difference of electric potential being relieved, removing a stress responsible perhaps for headache and a depressed feeling, and finally, there is a very important chemical effect by which the air is freshened There is no doubt that the rapid passage of water drops through air exerts a bracing effect upon it, which is probably due to the formation of peroxide of hydrogen which gives invigorating properties to the air, and, as is well known, will easily destroy unseen impurities These interesting facts, though affording, perhaps, feeble consolation to those who have gone to seaside and other places where the air is naturally pure, are probably of the greatest moment to those busy workers compelled to remain in the industrial hives of the towns, for by abundant rain a close, grimy, stifling atmosphere is thoroughly washed and freed from all impurities and made healthy, bracing, and bright.

MENTAL DISORDERS OF CHILDREN

Professor F X. Dercum of Philadelphia has contributed to the *Philadelphia Medical Journal* of July 19th and 26th last an important paper on the mental disorders of children in which an attempt is made to reduce to order from a condition of something like chaos this complicated and somewhat neglected subject and to point out some of the natural characteristics and affinities of the groups of nervous affections concerned Childhood is taken as embracing the period from birth to puberty It is pointed out that idiocy and imbecility are met with in children, but that insanity as ordinarily understood is rare The following four classes of idiots are recognised—viz, first, idiots with morphological anomalies of cranial, facial, and bodily formation, but without gross destruction of parts of the brain—e g, those of the microcephalic and "Mongolian" types, secondly, idiots with gross cerebral lesions resulting in paralysis and contractures—e.g, many epileptic, paralytic, syphilitic, and traumatic cases of idiocy, thirdly, cretins, and, fourthly, amaurotic idiots belonging to the "family" type With this last form of idiocy several children of one family are affected As a rule, adds Professor Dercum, nothing special is noted in patients of the last class until the child is about six months old, when arrest and deterioration of development supervene in association with progressive blindness and death follows shortly after This affection is essentially progressive, and destructive changes have been described as present in the nerve cells of the cerebral cortex, basal ganglia, and spinal cord The last two forms of idiocy enumerated above are, says Professor Dercum, distinctive forms which bear no relation to the first two forms or to each other Children, it is pointed out, suffer quite frequently from delirium and mental confusion and occasionally also from stupor These three forms of mental disturbance constitute another group of the mental affections of childhood. Such disturbances may occur as the result of febrile disease, shock, injury, fear, or prolonged excitement. Vivid hallucinations are developed and the child appears to be in a condition of unreasoning fright or terror Melancholia, mania, and progressive systematised delusions like those of paranoia form a third group of affections They are met with rarely in childhood, probably because of the incompletely developed condition of the brain and ego before adolescence Insanity may be foreshadowed in childhood but is seldom developed until after puberty Suicide in children is very rare as an outcome of melancholia. Some children exhibit neurasthenic symptoms in the form of *abnormal fears*, *painful indecision*, and *strong impulses* to destructive and criminal acts Such symptoms, vague at first, may prove to be the prodromata of a serious form of mental degeneration coming on in after years—viz., dementia præcox. At the approach of puberty such children are liable to exhibit periods of great exaltation and depression of spirits or of intellectual precocity and promise Within a few months or in one or two years, however signs of mental dulness and deterioration will appear If concomitant physical disturbances such as insomnia and cephalalgia, loss of appetite and feeble circulation are present there is danger of threatened mental breakdown and dementia. The most potent favouring cause of insanity in these cases is the presence of an hereditary taint. The case will then probably develop into one or other form of dementia præcox, which constitutes another group of the mental affections of childhood or youth Among the neurasthenic group of symptoms Professor Dercum also includes incorrigible tendencies to vagabondage and prostitution in young persons of both sexes. It is important, *concludes Professor* Dercum, that all neurasthenic symptoms should be diagnosed and treated early Children with finer intellectual endowments than their fellows require especial care when suffering from such symptoms, and their treatment should consist mainly in rest from work or study out-of door living and occupation, massage and hydro-therapeutics, a generous diet, and the administration of tonics and laxatives to correct anæmia and to prevent the accumulation of auto-intoxication products in the bowel In cases with a tendency to stupor good results have sometimes followed thyroid medication

THE PISTOL AGAIN

WE have not referred to this subject recently but the newspapers on Monday August 18th, contained details of no less than three revolver tragedies which so forcibly illustrate the dangers caused by the unrestricted sale and carrying of firearms that we desire to call special attention to them The first case is that of the gentleman who was shot in Gloucestershire by a friend with whom he was bicycling after which the murderer travelled to London and committed suicide at a hotel. Two deaths are thus recorded with regard to which the unrestricted carrying of the revolver is the important point for the position of the parties suggests that the mere cheapness of firearms was not a fact which influenced them. This points *to the desirability of* a licence for carrying pistols being issued upon terms implying some publicity and more inquiry into the character of the applicant than is the case with a gun licence. In this instance it will be observed two pistols played their part, for the murderer left the first at the scene of his crime but had no difficulty in surreptitiously borrowing another from his brother on returning to London It would be difficult to suggest that revolvers are necessary articles which these gentlemen lawfully carried for some useful purpose. In the second case to which we call attention a man at Coventry employed in the cycle trade called at a house where his wife was employed as a nurse in order to persuade her to resume cohabitation with him. This she refused to do, so he proceeded to shoot her inflicting a severe wound while he followed his attempt at murder by killing himself We ask if there is any reason why a man such as this should be able to buy a pistol for 5s without any questions being asked as to his identity his character or his intentions? In the third case, which was reported in the evening newspapers upon the day mentioned, a ship's cook was charged at the Thames Police court with attempting to murder a flower girl who had refused to marry him with causing bodily harm to two other flower girls, and with attempting to commit suicide. The prisoner according to the evidence given, shot the first girl after calling her towards him pursued the others as they ran away firing several shots at them of which two took effect, while the others apparently spent themselves in the public street without happening to do any harm and then so we gather a miss fire prevented the final tragedy As these cases are all still the subject of inquiry we add no more with regard to them except to express a wish that juries should realise in all cases the unnecessary ease with which firearms can be bought and the danger thus inflicted on the community Juries presentments are not perhaps very effective in promoting legislation but they play their part in calling attention to scandals and have some influence on public, if not on official opinion Three deaths and four woundings make a long list to be recorded in a single day and no doubt many such cases do not find their way into the London newspapers, to which alone upon this occasion we have referred

THE DISTRIBUTION OF PLAGUE

A TELEGRAM from the *Governor of the Mauritius*, received at the Colonial Office on August 16th states that for the week ending August 15th there was 1 case of bubonic plague and no death. As regards Egypt a Reuter's telegram from Cairo, dated August 17th states that the total number of cases since April 7th is 279 of which 156 have ended fatally As regards Hong kong a telegram from the officer administering the Government received at the Colonial Office on August 19th states that for the week ending August 16th there were 12 cases of plague and 12 deaths.

THE BRITISH PHARMACEUTICAL CONFERENCE AT DUNDEE

A VERY successful meeting of the British Pharmaceutical Conference was held in Dundee during last week. The proceedings commenced by an address from the President, Mr G C Druce, M A. F L S which was delivered on Tuesday evening August 12th, before a large gathering in the Dundee University College. On the last occasion of the visit of the members of the British Pharmaceutical Conference to Dundee, which was in 1867 the late Professor Bentley was elected President, and he chose for his address the subject of botany considered practically and scientifically as an aid to the pharmacist. Since that time the business of the pharmacist has like most other businesses felt the pressure of increasing competition, and nowadays it is but few pharmacists who have the opportunity of devoting any time to the study of systematic botany however much that study may be calculated to enlighten him as to the medicinal properties of plants To the modern pharmacist unless such study be a hobby it would mean the absorption of so much time which he could otherwise devote to the subjects—to mention one chemistry—which more closely concern the practical side of his vocation The President of the Pharmaceutical Conference this year on the occasion of its thirty ninth annual meeting like the President of the last meeting held in Dundee in 1867 is an earnest student of systematic botany and it might have been expected therefore that he would endorse much that the late Professor Bentley had to say on the previous occasion, and such was the case He described the progress of Scottish botany mentioning the work of botanists in Scotland and in alluding to the Scottish flora stated that Scotland has practically three-fourths of the plants known to grow in the British Isles. He concluded with some remarks emphasising the intellectual value and physical gain which the student of field botany might derive from a study of botany in the field. Such a study was not demanded for examinational purposes but it developed the powers of observation stimulating the faculty of exploration and was thus calculated to lighten to some extent the gloom of ignorance which enshroud some of Nature's problems" At the business section of the meeting a series of excellent papers were read and discussed.

Amongst the more important were those [illegible] official preparations, tasteless cascara preparations, alcoholic extracts, the preparation of galenicals, and other subjects of obvious practical concern to the pharmacist. Altogether, a very useful number of papers was read before the conference, followed by instructive discussion, and the year-book of the conference in which these proceedings will be published promises to be not less interesting than any of those of previous years.

THE PREVALENCE OF SMALL-POX

THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned. On Saturday, August 16th, there were 6 fresh cases, on Sunday, the 17th, there were 3 fresh cases, on Monday, the 18th, there were 3 fresh cases, on Tuesday, the 19th, there were 2 fresh cases, and on Wednesday, the 20th, there were 2 fresh cases.

THE USE OF NARCOTICS IN THE TREATMENT OF INSOMNIA IN THE EARLY STAGES OF INSANITY

DR. HENRY RAYNER has published a paper on this important subject in the July number of the *Journal of Mental Science* The fact that deprivation of sleep produces more distress and a more speedy fatal termination than deprivation of food is proof of the predominant need of sleep by the brain and body In cases of insomnia of some duration there is, says Dr Rayner, a general disorder of nutrition, and this is nowhere more marked than in cases of incipient or threatened insanity in which wasting rapidly follows upon insomnia. The drugs generally used in procuring sleep, such as morphia, chloral, and sulphonal, adds Dr Rayner, have an injurious effect on the nutrition of the body, and their dosage has to be increased to secure sleep if the drug has to be used for protracted periods. Such disadvantages, however, can be avoided by using prolonged baths and gentle massage as a sedative and hypnotic measure, as they not only induce sleep but improve bodily nutrition by promoting elimination of waste products. Narcotics, it is also argued, depress the cardiac, vaso-motor, and respiratory centres The beneficial effects of narcotics, however, appear to be undoubted, but these effects are regarded by Dr Rayner as being obtained at the expense of the brain, the nutrition and repair of which get slowly impaired by the use of narcotics. "My individual experience has led me gradually to discard the use of narcotics altogether in narcotic dosage, and to use them only at rare intervals in the hypnotic form and then only in the form of bromide or alcohol' Dr Rayner points out that many practitioners are too prone to use morphia or opium when insomnia exists and that the temporary benefit which follows as regards the restoration of sleep is often neutralised by the injurious after-effects resulting from the use of this drug In the discussion which followed the reading of the communication at a general meeting of the Medico-Psychological Association in London, Dr G Fielding Blandford stated that the use of hypnotics was often imperative in the insomnia of early or threatened mental disorder, and that the benefit was very great and material. Paraldehyde had in his experience always proved a safe and excellent hypnotic Dr G H. Savage emphasised the importance of procuring sleep in such cases if the threatened mental breakdown was to be averted, and stated that opiates and hypnotics were absolutely necessary Hydrotherapy also was a valuable aid to procuring sleep in restless and agitated patients, and where mental distress was extreme he had seen the best results follow the administration of large doses of narcotics. Dr Fletcher Beach concurred in the view that hypnotics, especially sulphonal, were beneficial in cases

sleep

CHOLERA IN EGYPT

A REUTER'S telegram, dated August 17th, states that the total number of cases of cholera existing in Egypt at that date was 381. In Cairo on August 16th there were 32 cases with 23 deaths, at Alexandria 1 case was notified. The total number of cases since July 15th has been 2016, of which 1509 have proved fatal.

THE PREVENTION OF ENTERIC FEVER IN ARMIES

IT will be remembered that when Dr Leigh Canney put forward his scheme for safeguarding an army against enteric fever by ensuring that troops engaged on field service should be supplied with boiled water we strongly urged that his plan, instead of being simply talked about, should be practically tried. We are very glad to learn, therefore, that the War Office authorities have determined on doing this an that all the necessary apparatus and equipment for ster lising water will be made available for the purpose, wh an opportunity occurs for the experiment There c be very little doubt, as far as the prevalence of epider typhoid fever of armies is concerned, about the part playe by contaminated water Sudden and severe outbreaks of enteric fever are often neither more nor less than examples of wholesale water poisoning

A TESTICULAR CYST CONTAINING ACARI

IN the August number of the *Quarterly Medical Journal* Mr R. J Pye-Smith of Sheffield describes what is believed to be a unique case In July, 1899, he was consulted by a medical man, aged 34 years, who several years previously had spent a short time in India and whilst there had on one occasion been catheterised for retention of urine during an attack of fever The patient was now suffering from a cyst of the right testicle which he had first noticed six years before, and it had gradually increased in size, more rapidly during the last year It caused but little inconvenience and no pain or other appreciable symptoms. Mr Pye-Smith punctured the sac with a trocar and cannula and drew of two and a quarter ounces of a watery, fairly opalescer fluid. This fluid was examined microscopically by Dr (Monro Hector who found that it contained, in addition many spermatozoa (still active but not very vigorous), nun rous living acari varying from 0 15 to 0 30 millimetre length and about 0 10 millimetre broad, he estimated t there were about 800 acari in the total contents of the cyst. On the advice of Mr A. D Michael, F Z S, the specimens were submitted to Dr E Trouessart of Paris who examined them and published an illustrated description of the acarus in the *Archives de Parasitologie*, No 3, 1902. He recognised it as new to naturalists (this department of the fauna of India has been very little studied) and he has classified it as a sarcoptide of the sub family tyroglyphinæ, nearly related to histiogaster carpio (Kramer), but a new variety, he therefore proposed to call it "histiogaster spermaticus." The measurements just given show that it is decidedly smaller than the ordinary itch insect which is itself so minute as to be barely visible to the naked eye. The itch insect also has its length and breadth nearly equal, whereas the outline of the new acarus is distinctly elongated. To account for its presence in the cyst Dr Trouessart suggests that an egg bearing female was adhering to the catheter which the patient had passed in India, that she attached herself to the urethral mucous membrane, entered one of the ejaculator ducts, and followed the vas deferens till she reached th epididymis, where she probably commenced to lay her egg and the infarct thus produced caused the rupture of the mucous membrane and the formation of the cyst.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE

AN office has been opened at Madrid to secure accommodation for members who propose to attend the Fourteenth International Congress of Medicine which will be held next April. Applications should be made direct to the secretary Bureau des Logements, Faculté de Médecine, Madrid Intending visitors to Madrid should not delay too long in making application, as it seems probable that the housing accommodation will be strained to the uttermost during the congress week.

SPOTTED FEVER OF THE ROCKY MOUNTAINS

AN interesting account of this disease is given by Wilson and Chowning in a report to the Montana State Board of Health[1] The disease occurs in a very limited tract of country in the Bitter Root Mountains and is characterised by rigors, high temperature, and the recurrence of a macular rash, at first rose-coloured and discrete but afterwards purplish and nearly confluent. The rash commences on the second to the fifth day about the wrists, ankles and back, but afterwards extends all over the body The disease lasts for two weeks and then begins to subside by lysis and convalescence commences about the end of the fourth week. The disease only occurs in the spring and has a mortality of from 70 to 80 per cent. No bacterial form could be isolated but there are present in the blood protozoan parasites not unlike the pyrosoma bigeminum of Texas fever The disease is not contagious, but in all cases examined there were small wounds of the skin said to have been caused by the bites of ticks, which are numerous in the locality and appear in the spring as soon as the snow melts. It is suggested therefore, that this remarkable disease is due to a protozoan parasite, infection with which is occasioned by the bite of a tick

AMAUROTIC FAMILY IDIOCY

AMAUROTIC family idiocy is a rare condition which has been observed in Jewish children. It was first described in 1871 by Mr Waren Tay since then about 68 cases have been recorded. In the *New York Medical Journal* of July 12th Dr A. Hymanson has published the following case A male infant whose parents were Russian Jews appeared normal until the eighth month when he ceased to take any interest in his surroundings. He would not raise his head and made purposeless movements of the limbs The head was large, measuring 19 inches in circumference. The fontanelles were prominent and widely open but at the age of 10 months they were gradually closing At the age of 15 months he could not hold his head up it was usually thrown backwards. He was very anæmic, his muscles daily became weaker and more flabby and spontaneous movements gradually ceased. He had a vacant look and seemed to see light but did not recognise his parents. He seemed to be deaf but became frightened when anyone knocked at the door During sleep the eyes and mouth were wide open. The pupils were slightly contracted and did not react to light. The fundi showed changes exactly similar to those described by Mr Waren Tay Corresponding to the macula lutea of each eye was a large bluish-white spot about twice the size of the optic disc. At its centre was a brownish red circular dot. The optic discs were in a state of grey atrophy and the calibre of the vessels was markedly reduced. The child died at the age of 19 months Two weeks before death there was great anorexia. He was much emaciated could hardly move his limbs and had gluteal bed sores The temperature was subnormal 97.5° to 98° F A necropsy was refused. Of the 68 recorded cases 40 are known to have been fatal the result in the others is unknown. The family predisposition is shown by the fact that 28 cases occurred in 18 families. 30 cases were observed in America, 11 in England, 14 in Germany and the remainder in other countries The necropsies have not shown any abnormality in the form or structure of the cerebral convolutions. Thus the etiology and pathology are unknown. The chief clinical features are idiocy weakness of all the muscles terminating in paralysis, gradual loss of sight, characteristic changes in the macula lutea, marasmus and death at the end of the second year

LEUCOCYTE CHARTS IN PNEUMONIA

IT has been known for a long time that the leucocytes in the blood are increased in pneumonia, and Dr J T Hewetson of Birmingham, writing in the August number of the *Birmingham Medical Review* recommends the use of charts or graphic curves showing the daily variations in their number as an important element in the diagnosis and prognosis of the disease. He holds that the information obtained by stained blood films is of less value in pneumonia than that derived from quantitative estimation of the leucocytes. He gives illustrations of charts containing three curves showing simultaneously for each day the highest pulse-rate and temperature and the degree of leucocytosis once he adds a fourth line—namely a respiration curve. The curves are not superposed but are kept quite apart, one above another with the same vertical lines for all. The leucocytosis scale has 5000 per cubic millimetre as the starting point and usually ascends by steps of 5000 with an upward limit of 30 000 but in one case the scale ascends by steps of 10 000 to an upper limit of 80 000. In moderately severe and uncomplicated pneumonia there is a rapid diminution in the number of the leucocytes after the crisis the average proportion per cubic millimetre being once more established. In severe pneumonia the leucocyte numeral is maintained for several days after the crisis and the fall to normal is gradual. As a diagnostic means in the early stage of pneumonia before the appearance of physical signs the presence of leucocytosis would exclude typhoid fever malaria, and influenza. *The leucocytosis of pneumonia is due entirely to* an increase of the polynuclear finely granular oxyphiles it usually rises steadily day by day reaching a maximum about the period of the crisis.

WE have received a copy of the Transactions of the British Congress on Tuberculosis held in London in July 1901 The Transactions make four large volumes, of which Volume II. containing the Transactions in the State Section, edited by Dr H. T Bulstrode, and Volume III containing the Transactions in the Medical Section edited by Sir Hugh Beevor and Dr Hector Mackenzie and in the Pathological Section edited by Dr J J Perkin. are the largest and most important. The Transactions are of great interest and will receive detailed consideration.

IT has been decided to hold the next meeting of the International Otological Congress at Bordeaux in 1904, instead of in 1903, as originally arranged on account of the International Medical Congress at Madrid being fixed for next April.

A CHARTER has been granted by His Majesty the King to the British Academy—a body formed for the promotion of historical philosophical and philological study The names of the 49 first Fellows of the British Academy include most of our best known scholars in the three departments of learning specified. Pure literature is not recognised in the new corporation, while that division of natural philosophy which is usually termed "natural science" will continue to supply the Royal Society with illustrious names

---

[1] Journal of the American Medical Association, July 19th 1902, p. 131.

THE *London Gazette* of August 15th contains the official announcement of the dignity of knighthood being conferred upon the Honourable Henry Normand MacLaurin, LL D, M D Edin, M.A., Chancellor of the University of Sydney and Member of the Legislative Council of the State of New South Wales, and upon Mr John Logan Campbell, M D, late Mayor of Auckland, in the Colony of New Zealand

Mr Norman Hay Forbes, F R C S Edin, has been appointed a Knight of Grace of the Order of St. John of Jerusalem in England

THE Duke of Bedford has promised an annual subscription of £1000 per annum for three years to the Cancer Research Fund.

Dr W S Playfair's many friends will be glad to learn that he is now entirely restored to health

Looking Back.

FROM

THE LANCET, *SATURDAY, AUGUST 21,* 1824

PHARMACEUTICAL CHEMISTRY

Hydrocyanic Acid

In a former number, we announced to our readers the test which M DUBLANC, of Paris, had discovered, for detecting the presence of acetate of morphine The test which this gentleman proposed is the tincture of galls, made with pure alcohol, but we have stated the objections which exist to this substance being used for that purpose, and have shown that iodine is far superior, either to the tincture of galls or ammonia, for detecting the presence of morphine, or any of its preparations We intend at present to allude to some experiments which have lately been made, by M LASSAIGNE, with a view of ascertaining the presence of hydrocyanic acid in animals which have been poisoned by this substance The test which is usually made use of for this purpose is the sulphate of iron, and the manner in which the experiment is conducted is as follows a little potash is put into the liquid which is supposed to contain some of the acid, and then some persulphate of iron, dissolved in water, is poured into this, when a beautiful blue colour manifests itself if there is any acid present The intensity of the colour varies according to the respective quantities of water and acid, and if there is but a slight quantity of the latter, some hours frequently elapse from the experiment before the blue colour is to be seen But M LASSAIGNE, in his experiments, tried another test, with which it is possible to detect twice as small a quantity of the acid as with the sulphate of iron M LASSAIGNE'S method is as follows some potash is to be put into the liquid supposed to contain the acid, so as to slightly alkalize it, to this a few drops of a solution of sulphate of copper are added, and then sufficient hydrochloric acid to re dissolve the excess of oxide of copper which has been precipitated by alkali, the liquid instantly assumes a milky appearance, more or less intense according to the hydrocyanic acid which it contains. A solution of nitrate of silver is also a very delicate test for discovering, in distilled water, the existence of the hydrocyanic acid, but as the product which is obtained possesses properties which are common to it and the chlorate of silver with which it may be confounded the copper is to be preferred The acid which M LASSAIGNE employed was the pure hydrocyanic acid, prepared according to GAY LUSSAC'S method, and which was mixed with five times its weight of water, in order to prevent its too speedy decomposition

From M LASSAIGNE'S researches it appears,

I. That it is possible to detect in a distilled liquid hydrocyanic acid in the proportion of a $\frac{1}{10000}$ or $\frac{1}{20000}$ of the weight of the water

II. That in the poisoning of animals by this acid, it is possible at the end of eighteen or forty eight hours, and even a longer time, to detect, by the processes mentioned above, the presence of this terrible poison

III That it is always in the viscera, where this substance has been first injected, that traces of it are to be found.

IV That in the head, spinal marrow, and heart, not the slightest quantity can be found, whilst in these organs the smell is so strong as to create a suspicion of its presence

ROWTON HOUSES, LIMITED

ANOTHER of those splendidly equipped buildings which have earned the name of "poor man's hotels" has just been opened at Fieldgate street, Whitechapel, London, E This is the fifth building of its kind and so excellently were the details of construction of the first Rowton House thought out that except as regards size not one of the buildings differs materially from any other

The present house is, however, larger than any of its predecessors, the first of which was opened at Vauxhall in 1893 with 475 cubicles, the second at King's Cross in 1895 with 677 cubicles, the third at Newington Butts in 1897 with 805 cubicles, the fourth at Hammersmith with 800 cubicles The fifth, the present building, has 816 cubicles

A full description of two of the Rowton houses will be found in previous issues of THE LANCET[1] and it is unnecessary to describe the new Rowton House in detail except as regards a few features In our report on the Rowton House in King's Cross road we called attention to the danger from infection of having one room only for the sorting of clean and the reception of dirty linen, while one lift carried both kinds of linen This serious defect in an otherwise perfectly arranged and admirably managed building has now been rectified and at the new Rowton House at Whitechapel not only are there distinct rooms for dirty and clean linen respectively, but separate lifts supply each room. Another matter on which Lord Rowton and his directors are to be congratulated is the provision of an open air lounge for the use of their tenants This is a most desirable addition to the building and is on a level with, and easily accessible from, the reading room On the opening day this lounge was decorated with flowers and plants of various kinds and it is to be hoped that these will become a permanent feature of this open air auxiliary to the reading room and building The sanitary arrangements show that the greatest care has been exercised in regard to the health of the inmates and the means of escape in case of fire are ample, though there is little risk of a serious fire occurring in one of these houses as they are practically fireproof From an artistic point of view the reading room is especially noteworthy, a large portion of the wall space being occupied by a series of panels emblematic of the Seasons These have been painted and presented to Rowton House by Mr H F Strachey Altogether the single working man of the poorer class in the East-End of London is to be congratulated upon a "home" where for 6*d* a night he can obtain a good bed in wholesome surroundings and good food at a very cheap rate, besides being surrounded with comforts which no other place of a similar kind, so far as we know, possesses But we must not forget that it is to Lord Rowton and his company that we owe this practical contribution to the solution of a difficult problem. The work which they have already done will not be forgotten, but practical and important as that work has been there is yet something still to be done —we mean the erection of a Rowton House for women We quite appreciate the difficulties of management of such a house, but a decent lodging house for women on the lines of Rowton Houses for men is a necessity Those who have so successfully planned and carried out Rowton Houses for men could we have no doubt, do the same for the other sex, at any rate, we hope that they will try

THE
BRITISH MEDICAL ASSOCIATION

MEETING AT MANCHESTER.

THE SECTIONS

MEDICINE.

FRIDAY AUGUST 1ST

THE sitting opened with

Demonstrations of Clinical Apparatus

Dr **JAMES MACKENZIE** (Burnley) demonstrated his Clinical Polygraph and Phlebograph. The sphygmograph, he remarked in the great majority of cases only took cognisance of the action of the left ventricle during a portion of the cardiac cycle. In order to get evidence of the action of the other chambers of the heart various methods had been devised. The clinical polygraph was intended to register on the same paper and at the same time as the radial pulse was registered, other movements due to the circulation or respiration. It consisted of an ordinary tambour attached to a sphygmograph in such a manner that the point of the lever of the tambour lay immediately above the lever of the sphygmograph. The tambour was connected by means of an elastic tube to a shallow open cup. This cup or receiver" was placed over any pulsating part and the movements were conveyed by the tube to the tambour A modification of the receiver was employed to register the movements of the lever Illustrations of its usefulness were given, and a case was cited illustrating how this method of observation recorded the action of the four chambers of the heart in a patient suffering from influenza, with a slow, irregular pulse. The facts noted in this case were that however irregular the action of the heart the ventricles always contracted together and the auricles always contracted together The ventricular movements were frequently slow and irregular while the auricular movements were faster and only rarely irregular It was pointed out that this peculiar discordance in the action of the chambers of the heart corresponded to the action of the heart chambers in digitalis poisoning and the suggestion was made that the influenza poison affected the heart like digitalis and not by means of the vagus nerve as was commonly assumed

Dr. **GEORGE HERSCHELL** (London) demonstrated the Tallquist Hæmoglobin Scale. The instrument consisted of a lithographed scale of tints. A drop of blood being placed upon a piece of white blotting paper it was compared with these and the colour which it matched showed the percentage of hæmoglobin. According to Cabot and Professor Sterling the error was so slight that it might safely be used for clinical purposes. The scales were supplied by Down Brothers, St. Thomas street E C.

Dr **DAVID DRUMMOND** (Newcastle) remarked that he was sure that the simplicity of the Tallquist hæmoglobin scale would make it a thoroughly useful test in the hands of the practitioner He wished to draw attention to the employment of the drop test, depending on the same principles as the hæmoglobin test, in detecting bile in the urine. For a long time he had been in the habit of using it in the wards and its extreme simplicity must commend it. A drop of urine containing bile on white blotting paper left a stain or disc that was almost characteristic, as the colouring matter was confined to the centre the periphery being practically colour free, whereas in the concentrated urine of dark colour the colour was shaded off gradually to the edge of the wet disc.

Dr **HERSCHELL** also exhibited an Apparatus for the Inflation of the Stomach with Air for the Detection of Gastric Atony and Dilatation of the Stomach. This procedure, he said was of great use in the differential diagnosis of gastroptosis and dilatation of the stomach and for the recognition of tumours of the stomach. He pointed out that the method of inflation by means of an effervescing powder as recommended by Professor T Clifford Allbutt, was obsolete among physicians who devoted their attention specially to disorders of the stomach The stomach in different patients varied considerably in size whereas the amount of gas disengaged from the bicarbonate of sodium was constant and thus efficient results could not be obtained. The apparatus shown consisted of a parolein atomiser connected to a Turck's double stomach tube. If the small tube was kept open and the air introduced through the other tube sufficient inflation of the stomach was produced without the possibility of over-distending that viscus. Moreover the visible cloud of atomised parolein enabled them to see that air was escaping and that the apparatus was working properly In practice the addition of menthol to the parolein conduced to the comfort of the patient during the operation There were in his (Dr Herschell's) view three degrees of gastric atony or motor insufficiency of the stomach. 1. Loss of *tonicity* in which the stomach was able to empty itself at the proper time but could not contract on its contents and allowed splashing to be elicited during the digestive period Most of the cases said to be dilated stomach by those who did not use the modern methods belonged to this class. Many of these cases were latent and showed no symptoms for a considerable time, but sooner or later they passed into the clinical period 2. Cases where the stomach could not empty itself before the next meal though it did so during the night. These cases, which he called stagnation myasthenia,' were on the borderland of dilatation. 3. True dilatation or retention myasthenia—i e. cases in which the stomach could not empty itself during the night and contained food residues at all times A stomach could only in his opinion, be said to be dilated when it contained food residues before breakfast, and no one had a right to diagnose dilated stomach unless he had examined the stomach before breakfast for food residues The neglect to do this made most of the literature on the subject fallacious. Cases in which no food residues were present before breakfast might be cases of atony (or more properly myasthenia gastrica with or without stagnation) but they ought not to be diagnosed as gastric dilatation unless there was definite retention of food.

Dr I **WALKER HALL** (Manchester) demonstrated his Purinometer an instrument employed for the clinical estimation of purin bodies in the urine

Dr J **DIXON MANN** (Manchester) congratulated Dr Walker Hall on the applicability of this process. So many of the methods were only available in a laboratory but this one was so simple that it could be readily employed at the bedside or in the consulting room.

Dr F J **POYNTON** (London) and Dr **ALEXANDER PAINE** (London) contributed a paper entitled

Observations upon Certain Forms of Arthritis

illustrated by lantern slides drawings and macroscopic preparations. The observations of the authors were chiefly confined to the rheumatic, rheumatoid, and septic types of arthritis. They commenced with an allusion to the isolation of a diplococcus from the throat of a man suffering from rheumatic angina, and the reproduction of rheumatic manifestations including polyarthritis by intravenous inoculation of this diplococcus into rabbits. The researches of Fritz Meyer and Loeffler were commented upon. As a result of a clinical pathological, and experimental study of rheumatic arthritis the authors had concluded (1) that the primary seat of deposit of the rheumatic micro-organism was in the synovial tissues (2) that the endothelium served as a barrier to its escape into the joint cavity and (3) that there was active phagocytosis both in the synovial tissues and also in the articular exudations when the diplococci did escape the endothelial barrier and reach the cavity of the joint. They thought it highly important to recognise that the escape of the micro-organism into the joint cavities was a vital and not a passive process and since rheumatic arthritis was such a transitory manifestation it was to be expected that the cultures would be often negative. In severe cases the diplococci were present in the exudation clinging to the fibrinous strands, and the endothelium was in such cases more or less destroyed In chronic rheumatic arthritis of long duration there occurred a perivascular fibrosis around the small blood vessels The contraction of this fibrous tissue diminished the lumen of these blood vessels and thus impaired the nutrition of the synovial tissues. They believed that this perivascular fibrosis explained to some extent the intractable nature of these forms of arthritis and their slow reaction to treatment. A very interesting type of arthritis had been especially described by Dr G F Still as occurring in childhood. It was characterised by much periarticular thickening The lymphatic gland and spleen were enlarged and the pericardium might be adherent. There was doubt as to how such cases should be classified whether as rheumatic, rheumatoid or as a special disease They had investigated one such case under the care of Dr F Parkes Weber during life with negative results, but there was, in spite of that, little doubt of their bacterial origin The observations of Dr Poynton and Dr Paine upon rheumatoid arthritis were limited to four particular points (1) whether or not there was a specific disease which could be called rheumatoid arthritis, (2) the production of rheumatoid arthritis by intravenous inoculation of a diplococcus, (3) the relation of the nervous to the arthritic phenomena, and (4) the relation of rheumatic fever to rheumatoid arthritis. Amongst all the uncertainty that surrounded the study of rheumatoid arthritis it seemed clear that many different infections might produce a rheumatoid arthritis Whether there was in addition to these a special disease still required elucidation It was also undoubted that various micro organisms injected into the blood stream might produce a rheumatoid arthritis, as they had demonstrated in January, 1902. Whether the nervous phenomena and the arthritis were the joint result of some peculiar poison acting upon both these tissues, or whether the arthritis was in reality neurotrophic, were questions which had to be approached at present with an unbiased mind, and they thought that the former view would prove to be the correct one. Rheumatoid arthritis following repeated attacks of rheumatic arthritis they thought might be the result of an intensified local virulence of the rheumatic infection and not due to a secondary infection This seemed probable to them because they had found that both simple and malignant endocarditis might result from inoculation with the diplococcus of rheumatic fever, and rheumatoid arthritis in rheumatic subjects appeared to them as the parallel in the joints to malignant endocarditis in the heart Upon two occasions they had isolated the pneumococcus from suppurative arthritis complicating pneumonia, which gave additional support to the writings of Leroux and of Dr Cave, Dr Nathan Raw, and Dr G R Murray of England. In the study of suppurative arthritis it had seemed best to abandon the use of the term "pus" and "septic," for these words were often used so loosely as to convey but little real information. Examples were given to illustrate that a detailed description of the exudations in arthritis was preferable to the use of these terms "pus" and "septic" Finally, the influence that was exerted upon methods of treatment by the recognition of a bacterial agent in many forms of arthritis was commented upon and exemplified by allusions to Menzer's specific rheumatic serum. The importance of prophylactics for the community and the individual, the necessity for a varied treatment based upon bacteriological inoculations, and the possibilities of surgical interference were also referred to

Dr **David Drummond** read a paper entitled,

Some Practical Remarks on the Diagnosis of Heart Disease

Brief reference was made to functional murmurs, and the point was insisted upon that a murmur did not necessarily indicate an organic lesion. The following phases of cardiac diagnosis were then discussed—the heart of alcoholism, of syphilis, and of kidney disease, cardiac dilatation, and mitral stenosis Great stress was laid upon the gravity of the prognosis in the case of a heart poisoned by alcohol, and the features of acute and chronic intoxication were considered. Dr Drummond urged that alcoholic excesses should be regarded as a common cause of valvular disease, affecting especially the mitral valves and producing thickening and regurgitation. Reasons were advanced for allocating to syphilis a prominent place in the pathology of heart disease, and it was claimed that the syphilitic heart should take its place beside the rheumatic and other well recognised forms of cardiac mischief the subject being illustrated by a detailed account of the clinical features of syphilitic aortic regurgitation In discussing the diagnosis of the renal heart stress was laid upon evidence of hypertrophy of the left ventricle with reduplication of the first sound. This led up to remarks upon cardiac dilatation, the diagnosis of which was discussed, and the following aphorism was advanced "Given obvious cardiac weakness, as shown by breathlessness dropsy, weak pulse of low tension, further weakened by exertion sufficient to embarrass, with great cardiac enlargement and systolic bruit either indistinct or absent, there is gross cardiac dilatation." Allusion was made to the diagnostic value of musical murmurs and a further communication on the subject was promised The paper terminated with a detailed description of the signs of mitral stenosis It was urged that in view of the fact that the characteristic murmur of mitral stenosis was so often absent the patient should be examined when lying on the left side and it was claimed that this manœuvre often brought into prominence the presystolic murmur

Dr F M **Sandwith** (Cairo) read a paper entitled

The Earliest Known Physician,

and exhibited a photograph of a portrait-fresco from his tomb[1] In his interesting "Medical History from the Earliest Times[2]" Dr E T Withington had given a frontispiece sketch and a short mention of the tomb of Sokhit-ni onkh who was the earliest physician in the world's history so far revealed Having in this way heard of the venerable colleague who lived some 5500 years ago Dr Sandwith thought it would interest many in the medical profession of the present day if he could re-discover his tomb, especially as he soon found that modern translators of the hieroglyphic text differed somewhat from the authorities quoted by Dr Withington. The tomb itself, the ruin of which still existed, was situated at Sakkarah, the necropolis (now mostly in ruins) of the mighty city of Memphis which flourished about B C 4000 and later, a few miles south of the present position of Cairo Dr Sandwith then described the tomb as "an oblong mastaba, 60 feet by 28 feet, quite plain, excepting for a well dug through the masonry The sarcophagus chamber is roughly hewn out of the limestone rock which forms the plateau of Sakkarah The name Sokhit-ni onkh signifies 'the man who is possessed of life,' and it must be remembered that the ancient Egyptians thought life and death were individual beings who could, if necessary, be eaten and swallowed. They also believed that every sick man was possessed by the spirit of a dead man or woman Who so likely, therefore, as the priest to be able to drive out the usurping spirit, which must be done before it was worth while to make any attempt at healing the sufferer's body which had been damaged by the occupation of the intruding spirit? In those days there were no physicians outside the priesthood, though bone-setters probably practised from the earliest times Sokhit-ni onkh was certainly a physician as well as a priest, because all the other titles after his name are only honorary ones given to every chieftain of high rank about the Court. His title as physician is *sennu*, which signifies wisdom or knowledge After the ordinary formulæ experts can read on the posts of the *Ka* or soul door the following sentences On the right, Pharaoh Sahura of the Fifth Dynasty is indicated as saying, 'His Majesty says to the chief physician Sokhit-ni onkh, Strength to thy nose, thou whose steps towards the West are beloved by the Gods and honourable old age as for a trusty and well beloved servant' The first words are an ordinary salutation to the living or the dead and are equivalent to wishing a cool breeze from the north, or air to breathe, from the Mediterranean The trusty servant refers to one who devoted himself during life to the king and after death to a god The physician then writes 'I worship the great King and I pray every god for Sahura, for he knows me and mine. Thus every wish from the mouth of His Majesty is realised for me, for the god (Anubis) has granted him to excel in medical affairs, because of the great veneration that he has for him more than for every other god Oh! you who love Ra, pray to every god for Sahura, who confers these benefits on me, for I am his trusty servant. I never do any one any harm.' In these last lines the physician requests all those who in the future will read his tombstone to add in their prayers the name of the son of Ra. On the left door-post the physician tells us what the King has done for him. The chief physician Sokhit-ni-onkh says of His Majesty 'It is thy double, oh friend of Ra, who hast divinely decreed to give me a stone door for this tomb in the cemetery' 'His Majesty [he further relates] ordered that two stone stelæ for doors should be brought from Tourah and that they should be erected in the interior of two niches of the Khaourri Sahura building [vision of the crown of Sahura] The chief taskmaster of two gangs of artisans [carpenters and sculptors] from the sacred workshops provided skilled labourers to execute the work. His Majesty was every day at the workyard seeing that religious decoration was carried out the whole day long His Majesty made them execute blue sculptured hieroglyphics of lapis lazuli.' It is clear from this that this Pharaoh profited by an expedition sent to the quarries of Tourah on the other side of the Nile to procure an extra stela which he gave to his physician, and allowed this to be erected while he was himself superintending the funeral chapel attached to his own future tomb There are other cases of a similar honour having been conferred by a Pharaoh on one of his favourites but I have not been able to hear of any other instance of the recipient being a physician. According to Petrie[2] the Fifth Dynasty started by tradition from a high priest of Heliopolis near Cairo and claimed divine descent from Ra. In earlier dynasties kings are always Horus kings or belonging to Horus and Set united, but in the Fifth Dynasty the king was first called 'Son of Ra. Sahura reigned for 13 years (3693–3680 B.C.) and his pyramid is believed to be the north one at Abusir—a few miles to the south of the great pyramids of Ghizeh. The most important event of his reign was his campaign in Sinai against the native tribes where he carved a rock tablet to commemorate his victory over the Menthu. The Fifth Dynasty is known to all travellers in Egypt by the Tomb of Tih and the Pyramid of Unas both at Sakkarah. The period was marked by its priestly character for religious foundations and fine tombs were considered more important than foreign wars or building great monuments and the earliest dated papyri come from this dynasty Dr Sandwith concluded by remarking that he did not pretend himself to any profound knowledge of Egyptology but he had had the good fortune of sitting at the feet of M Maspero who kindly allowed the photograph of the tomb to be taken. He was also greatly indebted to Mr Quibell who had supplied him with two photographs and other willing help On the stela, Dr Sandwith explained the physician stood with a sceptre in one hand and a wand in the other sometimes alone sometimes with his wife standing behind him. His name was always written plainly above his head but the wife's name had in every case been carefully erased which Dr Sandwith feared must mean that their revered predecessor was more fortunate at Court than in his home life.

---

[2] London: Scientific Press 1894

Dr HARRY CAMPBELL (London) read a paper on

Overlooked Forms of Graves's Disease

It was pointed out that Graves's disease was apt to pass unrecognised in its earlier phases and that it might remain in an immature stage for months or years, gradually subsiding or taking on further development in consequence of some acute illness fright, the climacteric, or other stress. When exophthalmos and pronounced thyroid enlargement were absent the disease was frequently overlooked. Extreme nervousness hand tremor and tachycardia, especially if occurring in a young woman should always lead to a search being made for other symptoms of the malady If these symptoms were lasting and not merely due to temporary excitement the diagnosis was almost certain, while it might be regarded as placed beyond doubt if emaciation, pigmentation of the skin, and profuse perspiration were likewise present. The most striking clinical feature of the disease was intense nervous agitation. The symptoms of Graves's disease were due to the presence in the blood owing to the occurrence of certain morbid changes in the thyroid gland of an excess of normal thyroid secretion or of perverted secretion, the effect of which was to cause the vital fire to flare up as it were exciting the tissues to a rabid katabolism and increasing the output of carbonic acid, urea, and other excreta. Such being the case, the question arose whether cases allied to Graves's disease might not occur owing not to an actual morbid condition of the thyroid gland, but to a mere physiological hyper activity of it. That the activity of this gland varied in different individuals there could be no doubt. Those with a congenitally sluggish thyroid were by nature phlegmatic, while those more actively disposed owed the circumstance to the possession of a more active thyroid. In like manner the same individual might differ at different times in respect of thyroidal activity and it might be believed that the gland might sometimes become so active as to induce a condition of thyroidism Several of the symptoms of the climacteric in woman might, as Dr H. Willoughby Gardner had suggested be explained in this way and many other cases suggested a similar explanation. It was necessary to remember however that such cases were not instance of true Graves's disease, in which the thyroid gland was not merely hyper active but was the seat of a profound organic change.

Dr D J CHOWRY MUTHU (Wells) read a paper entitled

Some Observations on the Results of the Treatment of 100 Cases of Pulmonary Tuberculosis treated by the Open air Method

There was a tendency in the present day he said to exaggerate the significance of the tubercle bacillus, but in his belief the soil was the more important factor—namely the causes which tended to weaken the resisting powers of the body—heredity alcoholic habits poverty unhealthy environment (such as overcrowding and defective ventilation) influenza, pleurisy pneumonia, overwork, worry anxiety and undue fatigue. Physical and mental strain tended to exhaust the nervous energy and to lower the vitality as much as anything He had met with three cases in which wives had nursed their tuberculous husbands all through their fatal illnesses but had escaped. No amount of exposure to infection would produce tuberculosis as long as the vital powers remained strong In 55 per cent. of his cases fever disappeared within six weeks. The usual method of taking the temperature was quite satisfactory He had found the rectal method neither trustworthy nor necessary After discussing the other symptoms and the physical signs the *rationale* of the open air treatment was discussed. As regarded the results achieved, out of 100 patients in all stages of the disease who had come under treatment in 28 the disease was actively arrested 40 were greatly benefited, and 11 were slightly benefited. The conclusions which Dr Chowry Muthu arrived at were (1) that the science of open air treatment was not yet perfect (2) that it was beneficial in the treatment of other diseases besides tuberculosis, and (3) that it was an important means of educating the people in healthy living

Dr A. MANTLE (Halifax) read a paper on the Vaso-motor Disturbances of the Stomach and Bowel

STATE MEDICINE.

FRIDAY, AUGUST 1ST

Mr C H. TATTERSALL (Salford) read a paper on

The Recent Outbreak of Arsenical Poisoning

which had been traced to the use of contaminated sugar in the manufacture of beer He stated that it was the custom of many English brewers to introduce artificial sugar into the mash tin in order to impart the necessary brightness to the beer The quantity employed varied from 6 per cent. in the case of the best kinds of beer to some 25 per cent. in the cheaper qualities. The sugar they used was either invertin prepared by treating cane sugar with sulphuric acid, or glucose, prepared by acting upon starch by sulphuric acid. Many firms required a guarantee that the acid which they purchased for this purpose was free from arsenic, but from March 1900 to November of the same year the acid supplied to one large factory had been manufactured from arsenical pyrites. The beer in the preparation of which this contaminated acid had been used was first put on the market in June 1900 the discriminating portion of the general public soon noted the ill effects following it consumption, and as a result drank less beer and it was the marked falling off in the returns that first attracted the attention of the brewers and also of the Customs department and led to the suspicion that something was wrong About the same time the marked increase in the number of cases of what appeared to be alcoholism and alcoholic peripheral neuritis led Dr E. S Reynolds the visiting physician to the Crumpsall workhouse hospital to investigate the matter thoroughly and as the result of his investigations to describe them as cases of arsenical poisoning Analyses of the beer supplies followed, and as the result of the analyses various amounts of arsenic were detected in many samples of beer and Mr Tattersall personally was of opinion that the recorded quantitative determinations all erred on the side of being too small the largest amount found was 1 5 grains per gallon. The marked influence which this outbreak of arsenical poisoning had exercised on the birth rate was also a point of great interest Allowing for the time that the contaminated beer was in circulation and the period of gestation the birth rate of Salford showed a decrease over the corresponding year of 4 2 per 1000 equivalent to 842 births. He deplored the fact that in spite of the number of deaths and the still greater number of individuals more or less severely injured the result of the consumption of the contaminated beer there was no system of notification which would have enabled the local public health authority to take steps to deal adequately with the outbreak, and he would suggest that some public department—for example, the Local Government Department—should be empowered to exercise a control over food stuffs generally and to seize and to summarily deal with such when that course appeared necessary in the interests of the public health.

---

[2] History of Egypt p 69 London 1899

In the absence of Professor SHERIDAN DELÉPINE (Manchester) photographic reproductions of his standards for the quantitative estimation of the arsenic in beer were exhibited

Professor J DIXON MANN (Manchester) then briefly recounted the various methods employed in the detection of arsenic in beer and its quantitative estimation and explained the process which he himself employed He quite agreed with Mr Tattersall that greater powers should be given to the public health authorities to deal with obviously injurious food stuffs, especially in such cases as were not provided for by the Sale of Food and Drugs Act.

Dr A. P LUFF (London), in the course of a few remarks, paid a highly appreciative tribute to the valuable and accurate work done by the Manchester scientists in the elucidation of the causes, &c, of the recent outbreak, especially by such workers as Sheridan Delépine, Dixon Mann, and Reynolds.

Dr E S REYNOLDS (Manchester) stated that cases of arsenical poisoning under the form of peripheral neuritis existed 20 years ago and were probably due to the arsenic now shown to be present in malt and that the recent outbreak due to excessively contaminated glucose should only be regarded as an incident—an incident, however, which provided the key to the situation Dr Reynolds also showed a remarkably fine series of lantern slides portraying the various chemical appearances observed during the outbreak.

Dr REGINALD A FARRAR (London), in a communication on

Plague as a Soil Infection,

stated his thesis as follows "Outbreaks of bubonic plague are dependent on the infection of soil with a specific microbe conveyed in the excreta of rats or other animals that have suffered from the disease Except in pneumonic cases, infection is generally the result of a direct inoculation from the soil Personal communication is a factor of relatively small importance in the spread of bubonic plague"

After a few remarks from the PRESIDENT, to which Dr FARRAR replied,

Dr J MILSON RHODES (Didsbury) communicated a paper on

Infant Mortality,

in which he referred to the Registrar General's report for the year 1900 (the last issued), which stated that of 927,062 children born no less than 142,012 were dead before they had reached one year of age. Sanitation had doubtless made enormous progress during the last half century, with the result that the general death rate had decreased from 22 0 to 18 2 per 1000, but that reduction did not apply to infants in the slightest degree The mortality to day was as high as it was 50 years ago—viz, 154—and in the year which he had quoted (1900) it was the highest on record—viz., 163 The variations in the death rates of various counties were very great. It was evident that the mortality was not due to climate, for counties in the same division showed very great variations—e g, the mortality of infants in Nottinghamshire was twice as great as that of Rutlandshire. Another fact that an inspection of the Registrar General's return brought out very strongly was that illiteracy amongst women and a high rate of infant mortality were very commonly found together, and he quoted statistics to show that in only one of 12 counties where the mortality was the lowest did the number of illiterates exceed 30 per 1000 In the case of the 12 highest in only three cases was it under, and in four cases it exceeded, 40 per 1000 Another fact that the table disclosed was that the counties with the highest mortality were those where the people were employed in mining or manufacturing The census returns showed that Nottinghamshire, Staffordshire, Warwickshire, and Lancashire, four counties having the highest infant death rate, were all counties where a very large number of women of the child bearing age were employed in weaving pottery, &c., and therefore employed in the great majority of cases away from their homes during the day, handing the so-called care of their little ones over to day baby farmers Bad as Lancashire was as a whole, Manchester was still worse, for the mortality in that city amounted to 198 per 1000 Cheetham, where the lowest rate of mortality was found associated with the lowest rate of illegitimacy, was a district largely occupied by Jews, and the fact that most Jewish women suckled their children no doubt played an important part in the reduction of the mortality On turning to the statistics of illegitimate children, the mortality was two or three times as great as in the case of the legitimate Taking the whole County Palatine, out of 268 infants of this class 91 died—that is, 33 per cent. Dr J Niven's report gave the proportion of deaths of illegitimate infants in the whole of Manchester as 46 per cent, in Ancoats the mortality rose as high as 60, and in Crumpsall 66 per cent. The principal causes of the high infant mortality were diarrhœa (38 per cent.) and bronchitis and broncho-pneumonia (17 per cent.) England was behind other countries in infant life protection. The so-called Infant Life Protection Act, 1897, provided that "all persons undertaking the care of *more than one infant* under the age of five in hire apart from their parents, or a single infant adopted for a lump sum not exceeding £20, shall notify the authorities" Miss Zanetti, the inspector to the local authority in Manchester, found that some of the worst houses got rid of one child so as to be out of the reach of the Act, and the clause that inspection should only take place where a child was adopted for a sum *less* than £20 was absurd. The International Congress for the Protection of Children, the Poor law Unions' Association, and the Central Poor-law Conferences, had all carried resolutions by at least two to one desiring the extension of the Act to all single child cases The Act was at present worse than nothing, for it made the public believe that security for these little ones existed where there was none. Such extension of the Act would, he felt sure, result in a reduction of the infant mortality, as it had done in France, and properly educated inspectors would be able to reach those having the care of the infants Inspection and education should travel together, and for this work he had no hesitation in saying that ladies were thoroughly competent. Who the administrative authority should be was another question. Personally he thought it a great mistake to make the guardians the responsible authority It would be more convenient for the district councils to be the registering, and the county councils the inspecting, authorities Dr Rhodes then moved the following —

> That the provisions of the Infant Life Protection Act should be extended to all single cases

This having been seconded was put to the meeting and carried

Dr MEREDITH YOUNG (Stockport) read a paper on

Further Control of Common Lodging houses

In urging the necessity for further control of common lodging houses he stated that the existing law was insufficient for the proper regulation of common lodging houses and their keepers. Once a registered common lodging house always a registered common lodging house, was a maxim which held good unless there were three convictions obtained against the keeper Any person might claim registration as the keeper if he produced his certificate of character signed by three small ratepayers, and unless the keeper were convicted three times of offences against the Public Health Act (Common Lodging house Provisions) He might be convicted of any other offences and might be utterly unsuitable for his office without running the risk of losing it. Apart from the obtaining of three convictions under the Public Health Act 1875, the local authority had no power under the general law to withhold the registration of any house as a common lodging house, provided that it had been inspected and approved by their officers, and provided that the keeper submitted his certificate of character in proper form It was only rarely that proceedings could be taken under the Housing of the Working Classes Acts, for a house might be quite unfit for use as a common lodging house long before it became unfit for human habitation. Again, there was no provision in the Public Health Acts for the licensing and registration of premises as common lodging houses for a short period of time. This was frequently necessary owing to a temporary influx of workers when some such work as railway construction, &c, was in hand. Another important point was that nothing appeared in the Public Health Acts or in the model by laws of the Local Government Board enabling local authorities to require means of escape in case of fire to be provided in common lodging houses. The Local Government Board memorandum on the requirements of common lodging houses entirely omitted this. Several cases had occurred recently where the absence of fire escape provision resulted in loss of life. In some of the larger common lodging houses used by males the want of urinal accommodation was often the cause of indecency and nuisance This again, was a matter unprovided for by legislation or in the Local Government Board memorandum, and surely in many cases the general decency and orderliness of common lodging houses was a matter requiring stringent measures for its improvement. All these improvements might be readily enforced by a simple legal enactment to the effect that all common lodging houses should be subject to an annual revision of their licences in the same way as slaughter houses under the Public Health Acts Amendment Act of 1890 licensed victuallers premises, music-halls, theatres, game-dealers and the like The experience in Stockport had been that the strict enforcement or special measures for securing better sanitation, better decency, and orderliness, and greater security against loss of life and property had been an easy matter when once the lever of annual registration was placed in the hands of the sanitary committee, while it was obvious that no hardship was entailed upon the good and well kept houses by such a measure

Dr F J H **COUTTS** (Blackpool) stated that the Blackpool council already possessed such powers as were suggested by Dr Young—viz. annual registration by the council, with the option when the licence was refused of appeal to the magistrates, and it was found that with the necessity for annual renewal of their licences before them common lodging house keepers were quite amenable to the suggestions of the local inspectors and willing to make such reasonable alterations and improvements as might be considered necessary

The proceedings then terminated with a hearty vote of thanks to the President and secretaries of the section.

PSYCHOLOGICAL MEDICINE.

FRIDAY AUGUST 1ST

Dr F W **MOTT** (London) opened a discussion on

Syphilis as a Cause of Insanity

The poison of syphilis he said, was remarkable for its persistency its potency and its prevalence. Owing to social conditions they could not regard syphilis as preventable, but the time had come when serious efforts should be made to diminish its prevalence. Syphilis acted in many ways as a cause of insanity During the secondary stage the anæmia and toxæmia which it produced acted as exciting causes of insanity in predisposed subjects, but over dosage with mercury was also a possible factor in some cases. Syphilitic brain disease consisted of inflammation of the supporting tissues of the brain and appeared in the form of basal meningitis gummata, arteritis and periarteritis. The worst forms of brain syphilis were those which occurred within the first four years after infection. Such cases usually ran a rapid course and were intractable to treatment Those forms of the disease in which there was a combination of endarteritis with gummatous meningitis simulated very closely general paralysis. The symptoms very often began with transitory aphasia, word blindness, and word-deafness, the paralyses which followed were coarse, and ocular paralysis was very common. Severe nocturnal headache occurred and attacks of exaltation and depression together with epileptiform fits were present, simulating general paralysis The disease was amenable to treatment by drugs and the symptoms in great measure coincided with the post mortem findings. The relation of general paralysis to syphilis was now an established fact of great importance The action of syphilis in producing general paralysis was limited to the brain of the civilised man for in savage races syphilis might be and often was common while general paralysis was rare The factors which in civilised life favoured the development of neurasthenia were capable, in cooperation with syphilis of producing general paralysis. Acquired or congenital syphilis was equally potent to cause general paralysis. General paralysis was pathologically a process of degeneration of the nervous system allied to tabes dorsalis a disease which was itself an outcome of syphilis. The Argyll Robertson pupil was one of the most characteristic signs observed in both affections. The occurrence of syphilitic infections could by careful investigation be traced in from 70 to 80 per cent. of cases of general paralysis. The symptoms of general paralysis however began to be apparent only several years after infection the average interval being 15 years. General paralysis was unknown where syphilis was unknown and was rare in the rural districts of Ireland and Sweden. It was also rare among priests, Quakers and women of the upper classes. General paralytics were immune to syphilitic inoculation. A number of statistical data were cited by Dr Mott from different observers and it was shown that the most recent observations concurred in assigning the first place among the etiological factors to syphilis. Juvenile general paralysis was almost invariably found to be a result of congenital syphilis and in 20 per cent. of the cases observed it was found that the fathers of the patients had had general paralysis. Dr Mott concluded by adopting for the purposes of raising a discussion, the thesis "No syphilis, no general paralysis."

Dr **JUDSON S BURY** (Manchester) said that congenital syphilis produced in infants a typical form of dementia described by him 20 years ago. He believed that general paralysis was largely but not exclusively due to syphilis

Dr J **WIGLESWORTH** (Rainhill Asylum) said that gross cerebral lesions due to syphilis, such as gummata and basal meningitis were not in his experience such common causes of mental disease as might be expected. The records of necropsies at Rainhill Asylum gave somewhat less than 1 per cent. of such cases. In the present state of their knowledge it would be going too far to take up the position of "No syphilis, no general paralysis." Many cases of juvenile general paralysis showed definite stigmata of congenital syphilis but many also showed no such stigmata, and he was inclined to regard some of these cases as having their origin in a vice of nutrition of the germ plasma caused by the action of the syphilitic poison. A similar vice of nutrition might give rise to idiocy in the offspring of syphilitic parents.

Dr G E. **SHUTTLEWORTH** (Richmond) stated that in his experience there was a very small proportion of idiots presenting actual stigmata of congenital syphilis not much exceeding 2 per cent. But considering the difficulty of obtaining correct family histories in such cases he was inclined to think that inherited syphilis played a larger part in the production of idiocy He had described in 1888 three or four cases of "syphilitic idiocy" which subsequently were placed under the name of "juvenile general paralysis."

Dr **FLETCHER BEACH** (Kingston) said that his experience coincided with that of Dr Shuttleworth as to the influence which syphilis played in the production of idiocy

Dr **OSCAR WOODS** (Cork) said that syphilis was very uncommon in the agricultural districts of Ireland and patients drawn from the same areas and admitted to the asylum under his care during the past 25 years very seldom had general paralysis. When general paralysis was present however a history of antecedent syphilis could be traced very frequently Even in large towns in Ireland such as Dublin and Belfast, general paralysis was uncommon

Dr **ROBERT JONES** (Claybury Asylum) agreed that syphilis was an important factor in general paralysis but could not accept the dictum "No syphilis no general paralysis." He looked upon overstrain rather than work as a factor in the production of the disease and pointed out that in persons whose nervous tissues had been devitalised by the syphilitic poison the physiological crises of life favoured the development of mental breakdown. The potency of the virus being so universally recognised the time had come, thought Dr Jones, when it would assist in the prevention of insanity and other diseases if some action could be taken by the legislature or by other means to prevent or to restrict the transmission of syphilis

Dr W **LLOYD ANDRIEZEN** (London) said that the offspring of syphilitic parents tended to develop various cerebral disorders and defects—idiocy imbecility epilepsy congenital weak mindedness and juvenile general paralysis—which were attributable to malnutrition of the germ or sperm cell or the embryo. Syphilitic encephalopathy was the result of recent syphilitic infection and was [illegible] by vascular change (endo- and periarteritis) and diffuse gummatous and round cell proliferation in the cerebral meninges from the direct action of the virus He could not positively assert whether the degenerative change in the cortical nerve cells and cranial nerves at this stage were primary or secondary to the above mentioned changes Small thromboses occurred in the affected vessels, especially in those supplying the basal ganglia. Hence resulted the stasis and inequality of the pupils ptosis, optic neuritis, trigeminal neuralgias, intense headache, and cephalic paræsthesiæ Attacks of vertigo and transitory loss of speech and paralysis occurred Such lesions and symptoms were syphilitic and many of them responded well to treatment with mercury and the iodides In patients with a predisposition to insanity, acute mental confusion, hallucinatory excitement, stupor, or agitated melancholia resulted Cases of the above description were absent in asylums but were met with in practice The symptoms developed at periods varying from two or three months to three or four years after infection Some of these cases were complicated with alcoholic or drug habits He preferred the title "syphilitic encephalopathy" to the term 'pseudo paresis" for such cases. That antecedent syphilis could be traced in from 70 to 80 per cent. of cases of general paralysis was true, but the etiology was a highly complex one, as alcoholic or sexual excess could be traced in many cases, the patients being persons of strong physique of ardent temperament, and of powerful animal and sexual appetites Tendencies to chronic renal disease and arterio sclerosis were also present, and in the parentage there were frequent histories of cerebral hæmorrhage thrombosis, and gross brain disease The form of heredity was a "congestive" or neuro vascular one and vesanic heredity occupied a place of secondary importance In one fifth of the cases of general paralysis there was no syphilis He had seen one case of malarial origin of general paralysis and on the whole was inclined to believe in a neurotic predisposition to general paralysis, probably inherited, and to regard syphilis as the main exciting cause, and alcohol, sexual excess, and overstrain as minor exciting causes capable of producing general paralysis without the assistance of syphilis

Mr C S MORRISON (Hereford) described cases of lead encephalopathy with all the classical symptoms of general paralysis

Dr E S REYNOLDS (Manchester) opposed the thesis, "No syphilis, no general paralysis," as unscientific and not in accordance with facts

Dr MAURICE CRAIG (London) supported the view that syphilis was the most important cause of general paralysis

Dr L. ALEXANDER (Hanwell) said that 88 per cent. of cases of general paralysis admitted into Hanwell Asylum were syphilitic.

Dr MOTT then briefly replied

Before the close of the meeting of this section a motion was unanimously passed to the following effect —

> That the Section of Psychological Medicine thinks it ought to point out that general paralysis a very grave and frequent form of brain disease, is largely due to syphilis and is therefore preventable We therefore the members strongly recommend that greater efforts should be made to arrest the transmission of syphilis and to stamp it out and we further urge that the attention of the legislature and of public bodies should be called to this important matter

PHYSIOLOGY AND ANATOMY

THURSDAY, JULY 31ST

Dr J S EDKINS (London) opened a discussion on

Intestinal Secretion and the Action of Drugs thereon.

He suggested two main points for discussion (1) the evidence of secretion of the so-called succus entericus , and (2) the functions of the normal intestinal epithelium. With regard to the succus entericus the more critically the evidence of its existence was examined the more doubtful did it become , thus, considering the histological evidence, the epithelium of Lieberkühn's glands or follicles was continuous with, and similar in structure to, that of the villi, and was different from that of the other digestive glands, the so-called Paneth cells with granules being only cells with mucigen granules Again considering the experimental evidence—viz , that of the Thiry Vella fistula and the effect of nerve stimulation—the results obtained by different observers were widely divergent, and the effect of cutting and stimulating the nerves was very difficult to separate from these of interference with blood supply which was very liable to occur during the operation Again, the chemical nature of the fluid obtained, which had a marked but variable alkalinity, and contained albumins, globulins, albumoses, and urea, suggested that it was of catarrhal origin, and Pregel in some experiments on a loop of lamb's gut admitted the existence of catarrh at the ends of the loop Dr Edkins was of opinion that all the so-called secretion or succus entericus was of catarrhal origin, the mucous membrane more or less denuded of its epithelium allowing the escape of lymph It was certain that the fluid always contained solid masses which on microscopical examination were found to consist of epithelium and masses of leucocytes Tubby and Manning in their case found the gut wall to present all the signs of chronic inflammation and Dr Edkins regarded the succus entericus obtained in experiments as the product of a chronic or "gleety" catarrh of the mucous membrane Considering the second question, that of the functions of the intestinal epithelium, it was certain that the epithelium could pass materials from the gut lumen into the blood vessels and effect changes in them in their passage, and recent work tended to show that the epithelium might produce some secretion which passed into the blood and stimulated the secretion of pancreatic juice, but the only evidence of the epithelium forming a substance to pass into the lumen was the existence of enterokinase, which was able to act on the inert pancreatic secretion and thus to develop its proteolytic properties, and it seemed possible that after all the conversion might be entirely due to leucocytes and not to the epithelium With regard to the action of drugs on the secretion of the succus entericus Edkins and Horder had studied the action of magnesium sulphate solution on an isolated loop, and taking a 10 per cent. solution had found an increase in the quantity of succus entericus amounting to as much as 70 per cent. and a very considerable increase in the suspended matter (large masses of leucocytes), and on subsequent histological examination of the gut denudation of the tips of the villi , they therefore explained the action of cathartics as due to the action on the epithelium, which was very sensitive to many reagents, allowing the lymph to flow freely outwards A further purgative effect was due to the peristalsis excited by absorption

Professor G N STEWART said that he agreed that the direct evidence of secretion was very scanty, but inquired as to the validity of the ' tapeworm " argument—that intestinal parasites could live in an isolated loop Since they were very sensitive to change in their medium it had been supposed that no very marked alteration of the normal conditions could exist in such a loop

Professor W STIRLING (Manchester) drew attention to the histological differences between the Lieberkühn's follicles of the small and large intestine and especially to the greater number of goblet cells in the latter He further cited the view of some French observers that the Peyer's patches being large collections of leucocytes might be of importance in liberating the enterokinase

Dr W E DIXON said that he had found on injecting purgatives into a loop as in Morot's experiments that if an irritant purgative were used there were signs of marked inflammation, whilst if purgative salts were used there was no inflammation but a marked increase of fluid, but far more than could be accounted for by osmosis

Professor W H THOMPSON (Belfast) suggested that it was possible that some condition for secretion had been hitherto overlooked and cited Pawlow's experiments on pancreatic secretion as an example of this

Dr EDKINS, in reply, stated that his position was a purely negative one and that he did not deny the existence of a normal intestinal secretion but affirmed that at present there was no evidence of it.

Dr LOUIS QUERTON read a paper on

Phenomènes Electriques qui accompagnent l'Oxydation de de l'Acide Oxalique produite par la Lumière,

showing that the action of light on solutions of oxalic acid was accompanied by the evolution of an electric current which could be demonstrated by a galvanometer and that this action could be augmented or delayed by certain other chemical reagents

Professor STEWART read a paper on

The Action of certain Hæmolytic Agents on Nucleated Blood Corpuscles,

in which he stated that mammalian red blood corpuscles presented certain properties which at first sight appeared to be vital phenomena and yet were certainly of physical origin—e g selective absorption. Thus, ammonium chloride was taken up by the corpuscles, while sodium chloride was not, and this happened in formaldehyde hardened corpuscles as well as in living ones In this research he showed that similar phenomena were found in the nucleated corpuscles of amphibia, birds, fœtal mammals and the corpuscles of bone marrow Of especial interest were the observations on the corpuscles of Necturus a tailed amphibian with very large corpuscles Many laking agents were investigated especially santonin bile-salts, ether and amyl alcohol. It had been suggested that many such reagents acted by rendering the corpuscles more permeable and thus practically placing the corpuscles in the same osmotic relations as if they were in distilled water—that was acting by a process of water laking Professor Stewart believed this to occur in some cases but in others—e.g sodium taurocholate—there was no entrance of water and yet hæmolysis occurred.

Dr F W EDRIDGE-GREEN (London) read a paper on

The Origin of a Visual Impulse

His view of the origin of visual impulses was that light falling upon the retina liberated visual purple from the rods and this being acted on by light stimulated chemically the cones and an impulse was transmitted along the visual path to the brain and received by a light perceptive centre which did not appreciate colour but simply light and shade Colour perception was due to a special centre separate from the visual centre but closely connected with it, a colour being simply a point of difference capable of being perceived by this centre

Dr W RAMSDEN (Oxford) described

Some New Properties of Urea (with Demonstrations)

Solutions of urea had a very marked action on proteids thus a solution of proteid to which urea was added did not coagulate on heating The coagula formed when solutions of native proteids were heated dissolved on the addition of urea solution gelatin was very readily dissolved by it. A dead frog placed in saturated urea solution soon became translucent and shortly fell to pieces Connective tissue was readily dissolved and this property would probably be useful for histological purposes. The myelin sheath of nerve was rapidly altered and presented similar appearances to those of degeneration. Urea converted native egg white into a jelly Dr Ramsden at first supposed that urea in these reactions was active as a base but further experiments negatived this view—for example, urea was equally active on proteid in acid solution Dr Ramsden considered that it might act by rendering the proteid more sensitive to the action of any acid or alkali present. He had prepared crystalline compounds of urea with proteids and palmitic acid.

FRIDAY AUGUST 1ST

Professor C S. SHERRINGTON (Liverpool) and Dr A. S. F GRÜNBAUM (Liverpool) opened a discussion on

The Motor Cortex as Exemplified in the Anthropoid Apes

in which they brought forward the result of their investigations on 13 chimpanzees two orangs, and one gorilla. They first described the technique of their experiments Stimulation was effected by Sherrington's unipolar method a large flat electrode being placed on the foot of the same side and a fine platinum wire with a small knob used for stimulation of the cortex, the arachnoid being opened and the fluid allowed to escape. The strength of current required was about the same as that for the cat and for the rhesus monkey The convolutions in the anthropoid approach the human type, but there was great liability to individual variation and frequent asymmetry which prevented them from being of great use as physiological landmarks Of greater utility were the genua of the Rolandic fissure, the lower genu marking the situation of neck and arm centres, the upper the body trunk or cruro-abdominal areas. On the mesial aspect the leg area extended for some distance, thus from below upwards the order was face neck, arm body and leg A most important point brought to light in these researches was that the excitable motor region, though extending deeply into the Rolandic or central sulcus did not extend on to the free surface of the post-central convolution, and this was in opposition to the results of previous observers The movements obtained from the different areas were broadly as follows in the face area eye, eyelid, nose, jaw vocal cords mastication and also movements of the mouth and tongue in the arm area shoulder elbow wrist, fingers and thumb in the leg area toes, ankle, knee, hip, in each case from above downwards. Movements of the anus were obtained by stimulation just at the border between the external and mesial surfaces of the hemisphere. A further difference from the results of other observers on the anthropoids was the ease with which epileptiform convulsions were obtained from the cortex. They had further studied the results of ablation of parts of the cortex and found that marked paralysis occurred from even a small lesion but that this was recovered from, and they had also observed almost complete recovery after double extirpation of the arm area. Professor Sherrington had also investigated the direct pyramidal tract in anthropoids and found that in the chimpanzee a ventral pyramidal tract occurred as in man, and like that of man was of very variable individual character

Dr CAMPBELL read a paper on the

Histological Features of the Regions of the Cortex in Anthropoids with Special Reference to the Varieties of Medullated Fibres and their Topographical Relations in the Cortex.

He found special characters in the motor region—viz. (1) the possession of a well marked zone layer or tangential field, (2) a supra radiary field and (3) a radiary zone of great depth and richness in nerve fibres or of great fibre-wealth" further there were large ganglion cells or cells of Betz in this region. These histological results were in complete accord with the experimental results of Professor Sherrington and Dr Grünbaum as the motor type of structure was bounded posteriorly by the fissure of Rolando and did not extend into the post-central convolution.

Professor SYMINGTON (Belfast) Dr W PAGE MAY (London) Professor W H. THOMPSON (Belfast), and Professor ARTHUR ROBINSON (London) joined in the discussion which followed.

Professor R. G ANDERSON read a paper on Occipital Condyles, illustrated by specimens and lantern slides

Professor SYMINGTON described the Topographical Relations of the Optic Radiation and illustrated his remarks by lantern slide photographs of sections of the human brain.

PATHOLOGY

FRIDAY AUGUST 1ST

Professor D J HAMILTON (Aberdeen) opened a discussion on

The Relationship between Human and Bovine Tuberculosis

His own experiments were still in progress and he was not at liberty to publish them at present. He reviewed at length the work done by various investigators on this subject and drew attention to the remarkable results of Koch and Schultz. Those results were uniform, and as they stood they justified the conclusions drawn from them which were recorded at the British Congress on Tuberculosis. These investigators failed to inoculate the calf with human tubercle bacillus by any means but they succeeded in producing tuberculosis from cultures of bovine tubercle and they concluded that the cow was immune to human but not to bovine tuberculosis. Professor Hamilton did not entirely agree with the reading of these experiments. In one of the inhalation experiments local infection had occurred in the lungs. Another observer had got similar results in pigs general tuberculosis having been produced by feeding these animals on human tuberculous sputum The speaker considered that there should be some common understanding on what was to be considered successful inoculation and what not. If it were agreed that a tuberculous growth at the seat of inoculation should not be considered successful inoculation then the majority of cases of human tuberculous infection must be looked upon as not inoculable, for here there was as a rule, only a local growth at the point of inoculation—e.g the lungs If extensive tuberculous lymphadenitis was produced in animals by inoculation this must be accepted as a successful inoculation on a new host. Probably in these animals the human bacillus had not yet become acclimatised to its surroundings. Experiments by other observers showed that the local infection from human tubercle produced in a calf was capable of producing general tuberculosis when transferred to another calf The human tubercle bacillus developed slowly in the calf at first, but in time produced general tuberculosis Chauveau had described numerous tubercles in the lungs of a calf by inhalation from human tubercle. This was at variance with the experience of other observers who found the mesenteric glands especially affected. He remarked upon the experiments of Professor Delépine Arloing had injected emulsion of human tubercle bacilli into the jugular vein of goats, calves sheep, asses rabbits, and guinea pigs The inoculation was positive in *all* cases without exception Young animals were more sensitive to the bacilli, the goat was more resistant than the calf or the sheep The bovine bacillus excited, as a rule, more acute and widespread disease than did the human, but the latter gained in virulence by inoculation from one calf to another Variation in the microscopical appearances were meaningless and mere differences in form or virulence were a poor basis on which to found a classification of species The human bacillus itself varied greatly in virulence from time to time. The question was not whether a given culture could be transferred, but whether any human tubercle bacilli could be transferred to another host without intervening conditions Professor Hamilton regretted that Koch and Schultz had not used tuberculous glands in their experiments

Professor SHERIDAN DELÉPINE (Manchester) congratulated Professor Hamilton on his admirable summing up of the position The experiments of Koch were so contradictory to general opinion and to the experiments of other observers that even his great name was not sufficient to weigh down the balance on his side. It must be recognised that different animals were not equally susceptible to organisms. He agreed with all that Professor Hamilton had said Personally he had been able to produce in the calf true tuberculosis from human bacilli and from this he got tubercle bacilli which were still more virulent. The virulence of the human bacillus was variable and in his own experiments he used a combination of tuberculous sputa from different sources

Dr T SHENNAN (Edinburgh) said that another criticism of Koch's work was that the bacillus tended to increase in virulence in passing through a series of animals of the same species and lost its virulence when transferred to an animal of another species The susceptibility of man was different from that of other animals Koch started his work from statistics, but Dr Shennan thought this was a mistake. In Germany cooked milk was used, in this country the milk was uncooked and open to all infection. It would therefore be expected if infection were carried by milk that it would be more common in this country, but, on the other hand bovine tuberculosis was less common here. Statistics had been compiled in the Edinburgh Children's Hospital and in the Great Ormond street Hospital in London to estimate the relative frequency of respiratory and intestinal tuberculosis, and others had been made in Birmingham and in Germany The results were similar in Edinburgh and London but were different in the other centres He referred to the investigations of Dr Bush of Philadelphia on the geographical distribution of tubercle in regard to meat and milk. He agreed with Professor Hamilton in regard to the personal equation of individual resistance. He then detailed three peculiar cases of tuberculosis, in one of which there were plaques in the peritoneum which he thought resembled bovine tuberculosis.

Professor NORTHRUP (New York) discussed the point of entrance of the tubercle bacillus He had studied this subject for 12 years at the Foundling Hospital at New York, and the material extended over 3000 post-mortem examinations in which there was 1 per cent of infants under three years in which the primary seat of tubercle was abdominal The oldest process was in the lymph nodes of the mesentery, and if this represented the primary source then the infants of New York were exposed to very small danger from milk.

Mr W HODGSON (Crewe) related an experiment in which a healthy cow was fed on human tuberculous lymphatic glands in a trench for six weeks. At the post-mortem examination the oldest tuberculous disease was found in the lungs and the most recent in the intestinal tract This showed that although the bacilli were taken in through the stomach they would proceed to the most suitable nidus before developing

Dr R MAGUIRE (London) pointed out a possible fallacy in these cases The inoculation might have been produced by inhalation during feeding on the tuberculous material.

Professor HAMILTON, in reply, said that he had seen the plaques described by Dr Shennan several times in the human subject, they were very common in the cow but the similarity of appearances was of little importance. The point of entrance of the bacillus was, as Professor Northrup had insisted, very important. In a large proportion of cases there was no lesion of the intestine, but in practically all cases the abdominal glands were enlarged and cheesy, while the lungs escaped in most experiments. Subcutaneous injection of bacilli produced pulmonary tuberculosis almost invariably His experience had taught him that the bacillus might not affect the point of inoculation but go elsewhere There was no hard and fast line

OPHTHALMOLOGY

FRIDAY, AUGUST 1ST

Dr JAMES TAYLOR (London) opened a discussion on

The Rarer Forms of Atrophy of the Optic Nerve

He began by thanking the officers of the section for the honour they had done him in inviting him to open this discussion and for their choice of a subject of interest both to physicians and surgeons and one on which they might give and receive mutual help and instruction He excluded from discussion, except for purposes of comparison, atrophy following neuritis the result of intracranial growth and atrophy (primary) resulting from tabes or general paralysis. At the same time he emphasised the importance of recognising the frequent occurrence of optic atrophy in general paralysis, he had made post-mortem examinations on several cases of general paralysis in which the mental symptoms had been present only a short time, although the patients had been blind in some instances for a considerable number of years It was also to be recognised that optic atrophy was not an uncommon result in the neuro retinitis occurring in Bright's disease and also in cases of glaucoma and of injuries to the optic nerve He referred first to the large class of cases of optic atrophy associated with disseminated sclerosis. These, he believed, were in most cases the result of a neuritis usually retro-bulbar in position, but in some cases obvious on account of redness and slight swelling of the disc. In some cases a central scotoma for colours was present, the pallor in these cases was slightly different from that in tabetic cases and the vessels were not so small. One very striking difference, also, was that in the vast majority of cases of optic atrophy in tabes the visual impairment went gradually but surely on to complete blindness, he had never in the numerous cases of disseminated sclerosis which he had observed seen complete blindness occur Indeed, one was often surprised at the very fair vision which coexisted with extreme pallor of the discs Dr Taylor next referred to cases of toxic amblyopia and the atrophy which frequently accompanied it, he referred to the small quantity of tobacco which might cause amblyopia if sugar be present in the urine and to one patient who had been attended for 20 years and had never used tobacco but who had glycosuria and central scotoma. He asked what was the factor which in some cases of toxic amblyopia prevented recovery and was the atrophy in these cases likely to be a progressive one? He next referred to cases of optic atrophy not preceded by neuritis, occurring as a result of pressure at the chiasma and referred to the frequency with which such cases came under observation with one eye already blind, while the other had the temporal "field" blind Dr Taylor also referred to a case of optic atrophy which he had seen occur in a case of ordinary left hemiplegia in which there was no hemianopsia, and to the likelihood that these cases were not uncommon He also referred to two cases of optic atrophy in young men the reason for which was obscure

Mr W T HOLMES SPICER (London) said that atrophy arising in disseminated sclerosis, though not always associated with much defect of vision, mostly began with a central scotoma which often became absolute, so that there was a resultant grave impairment of vision, though this rarely progressed to absolute loss of peripheral vision Many cases remained in this condition for years, he thought that the cause lay in islands of sclerosis in the optic nerve itself He could not agree to the doubts which Dr Taylor had thrown on the frequency of toxic atrophies. Difficulty often arose from the deceit of the patient This, again, accounted for much failure of treatment in such cases In diabetes he had no doubt that central scotoma occurred, yet this might be greatly exaggerated by the incidence of tobacco Many scattered and obscure cases, especially in young people, he thought to be connected with hereditary causes—Leber's disease. An anatomical explanation had been given for such cases in congenital deficiency of the walls of the optic foramen and contiguity of the nerve with the nasal sinuses He felt that this could not explain all

Dr EMRYS JONES (Manchester) said that he had noted a rare case of optic atrophy associated with dropping of fluid from the nose

Dr C O HAWTHORNE (London) had seen cases where blindness in one and loss of the temporal field in the other had occurred after erysipelas of the blind side, it was supposed that *the transference of the affection from one side to* the other was due to some sympathetic connexion. He had grave doubts as to the certainty of diagnosis of optic atrophy based upon the appearances of the optic discs alone and in the absence of other signs in vision and visual fields.

Dr A. BRONNER (Bradford) quite agreed with Dr Taylor that in many cases diagnosed as tobacco amblyopia the impaired vision was due to other causes many were due to commencing central retinal and choroidal changes which disappeared on the use of iodide of potassium It was important in all cases of optic atrophy to take out the field of vision for colours as well as for white by so doing very early changes could be noted

Dr G NEWTON PITT (London) believed that the relative frequency of central scotoma in disseminated sclerosis in cases published in England was small it was much higher on the continent. The pathological material available was very small indeed, which somewhat vitiated conclusions. He agreed that it was not justifiable to diagnose optic atrophy from disc colour alone there must also be diminution of the vision and field

Dr S LODGE (Bradford) noted the occasional occurrence of such cases with scotomata and contraction of fields in quite young people from 16 to 30 years of age. In two of these he had been able to obtain histories of toxic trade connexions and in others a record of like cases in other members of the family

Mr J HERBERT PARSONS (London) called attention to a tendency to put the lesions in all these cases in the optic nerve itself In many of them it was probably in the retina. The evidence in favour of this in the case of toxic amblyopias was increasing rapidly Attention was especially directed to the work of Birch Hirschfeld on the subject

Dr J G CLEGG thought that many of the cases of quite white discs with excellent vision were those of early tabes.

Mr N BISHOP HARMAN (London) said that he had for some time been unable to accept the current views of the pathology of optic atrophy in retro-bulbar neuritis &c., he believed it to be based upon an inaccurate appreciation of the ascertained facts of the development of the nervous connexions of the eye and of the theory of the neuron. The retina was known to arise as an outgrowth from the brain within this outgrowth nerve-cells gave rise to axons which grew centrally to make connexion with parts of the brain different from the site of origin of the evagination Thus the trophic centres for the optic nerve-fibres were the ganglion cells of the retina from which they were out growths the case was parallel with the relation of a posterior root ganglion cell to its central axon passing into the cord Thus degeneration of the optic fibres should be in the vast majority of cases ascending only, and they should look in cases of optic atrophy first to the retina for evidence of *damage. He believed that a rational classification could be* arrived at as follows 1. Primary damage in disease of the ganglion cells (*a*) from anæmia due to spasm of the retinal vessels from drugs as quinine, reflexly from cold and to general anæmia succeeding severe hæmorrhages febrile diseases, &c. and (*b*) from poisoning of the ganglion cells by drugs tobacco and lead, a view directly supported in the antidote of tobacco blindness strychnine, which was agreed to act directly upon nerve-cells. In all these cases the changes at the disc would be proportionate to the number of cells damaged, in cases of great loss of ganglion cells it was probable that the rapid destruction and swelling of the myelin sheaths of the degenerating fibres at the lamina cribrosa produced a mechanical choked disc. 2. Cases of damage to the optic nerve by contiguity of diseased structures or in general nerve changes producing islands of fibroid exaggeration and followed by obvious atrophy of the disc. Here ascending degeneration should be the earlier result, with a later degeneration of the axon segment next the trophic ganglion cell from disuse, a process the more easy owing to the special myelin sheathing of the optic nerve fibres.

Dr A. MCGILLIVRAY (Dundee) asked Mr Harman how he could explain undoubted optic atrophy following section of the nerve in fracture of the optic foramen if he believed only in ascending degeneration.

Mr HARMAN said that in these cases there was nothing to show that *the damage* was limited to the actual point of injury, exudation was just as certainly to be found within and around the optic sheath even to the disc which would explain the early onset of atrophy in some cases further he allowed the possibility of a degeneration of *the segment* twixt injury and trophic cell both from disuse and by reason of the arrangement of the myelin sheaths of the optic fibres.

Dr A. HILL GRIFFITH (Manchester) thought that the occurrence of atrophy after hæmorrhage, hæmatemesis &c. had been overlooked it certainly occurred He also noted the greater susceptibility of women to tobacco than men both in rapidity of onset and slightness of cause.

Dr MCGILLIVRAY said that though he had little experience of hysterical amblyopia in Dundee there were numerous cases of tobacco blindness in mill women, the liability he thought partly due to the late age of their indulgence

Dr TAYLOR, in replying, said that he did not mean to throw doubt on the frequency of occurrence of tobacco blindness, he felt that it was unduly credited with cases arising from other causes He had had no reply to his inquiry as to the progression and permanence of optic atrophy in these cases. As regards the greater susceptibility of women he noted also their readier reaction to alcohol poisoning as exemplified in the greater frequency of alcoholic neuritis amongst them.

DISEASES OF CHILDREN

FRIDAY AUGUST 1ST

Mr W ARBUTHNOT LANE (London) opened a discussion on

The Value of Physical Exercises in Diseases of the Respiratory Tract

He described the influence of systematic and regulated exercises upon the upper part of the respiratory passages and emphasised the positions which he had previously defined[1] in reference to the relationship of such exercises to naso-pharyngeal obstruction by adenoids, &c. He also discussed the several factors that modify the condition of the teeth and the digestion in patients suffering from respiratory incapacity together with the effects of such incapacity on the tendency to catarrhal processes. He advocated the study of the respiratory function with a view to treatment in each individual case.

Sir FELIX SEMON (London) had a high appreciation of the value of respiratory exercises. They had their own place and value, but he could not accept the view that they could overcome the mechanical obstruction produced by adenoid masses in the naso-pharynx

Professor BAGINSKY (Berlin) said that some children were the subjects of adenoids at the time of birth and in these cases at all events the condition would not be attributed to respiratory inefficiency He agreed that in many cases operations for adenoids were unnecessary a change to the seaside being often sufficient to cause their disappearance.

Dr J J COX (Manchester) endorsed this last statement *on the basis of* a considerable personal experience.

Dr HARRY CAMPBELL (London) directed attention to the feeding of children by soft food as an influence prejudicial to the development of the masticatory apparatus and argued that this led to imperfect expansion of the upper air passages

Dr SCANES SPICER (London) and Dr P MCBRIDE (Edinburgh) took part in the discussion

Mr MAYO COLLIER (London) said that neither Mr Lane nor any other surgeon had suggested that breathing exercises could cure well marked adenoid Sir Felix Semon's statement that nasal obstruction had no relation to the production of post nasal growths was unsupported by evidence. The experience of most surgeons was directly in the opposite direction. Nasal stenosis caused vascular engorgement in the post-nasal space and as further results catarrh and adenoid hypertrophy It was not necessary to nasal stenosis that there should be a definite bony or other form of tumour A lax atonic condition of the turbinal body with the vascular distension that was inevitable when the patient was lying down, and also in other circumstances, was quite sufficient to cause stenosis and to lead to disuse of the nasal airway As a matter of fact this was usually the condition present. The defective development of the upper jaw and palate which attended nasal stenosis Mr Collier attributed largely to atmospheric pressure

Mr ARBUTHNOT LANE replied

---

[1] THE LANCET Feb. 15th (p. 4[illegible]) and 22nd (p. 5[illegible]) 1902.

At a joint meeting with the Pathological Section

Dr J W **BALLANTYNE** (Edinburgh) opened a discussion on

The Congenital Diseases of Bone

After a brief sketch of the various stages in the ante natal history of bone Dr Ballantyne said that it was necessary to recognise the general principle that the effects upon the skeleton of prejudicial influences would be very different according to the stage at which such influences came into operation In the earliest stage the tendency would be to produce deformities or malformations, whilst it could only be when osseous tissue had been definitely formed that true diseases of bone could be produced Thus anencephaly resulted from an early arrest of the formative processes of a part of the skeleton, whilst cranio tabes was a morbid change in fully formed bone Between such extremes were intermediate links which might be viewed from either or both aspects This principle was advanced as bearing on the question of fœtal rickets and it was urged that provided the causes which produce rickets in extra uterine life came into operation during intra uterine existence the skeleton would necessarily be affected. There would be conditions of the cartilages and bones which might be called rickets and which etiologically were rickets. But in these conditions the histological changes might be expected to be different from those of extra uterine rickets because the bones had not reached a stage of development in which such changes could possibly be produced Various other early diseases of bone were described and illustrated by lantern slides and Dr Ballantyne concluded by emphasising the importance of the placenta in relation to the nutrition and development of the fœtus

Dr W **STOELTZNER** (Berlin) could not unreservedly accept Dr Ballantyne's classification of congenital bone disease He preferred to state only two groups—namely, (1) those due to arrest of periosteal formation and (2) those resulting from a general dystrophy On the question of fœtal rickets his appeal was to the microscope, and this never revealed the characteristic features of rickets. Numerous microscopical specimens were shown to support these views

Dr **JULES COMBY** (Paris) considered that the term "rickets" had been too generally applied to diseases affecting the skeleton in the early period of life The recognition of the influence of developmental defect, of syphilis, and the explanation of such conditions as achondroplasia were all steps in advance.

Professor **BAGINSKY** (Berlin) held very confidently that rickets might and did occur during intra uterine life He had satisfied himself on this point by repeated microscopical examinations He also described various clinical varieties of rickets as met with in young children.

LARYNGOLOGY

WEDNESDAY, JULY 30TH

Dr **EDWARD LAW** (London) showed a case of

Papillomatous Excrescences, or Ozænic Incrustations, or Chalky Deposits, or Other Lesion Low Down in the Trachea

The patient, a woman aged 36 years had suffered from ozæna since childhood and had to a great extent recovered under various methods of treatment, she was anxious to get quite well if possible and had recently lost her sense of smell. Formerly the voice was very husky and hoarse but not recently, and laughing often produced a fit of coughing From the age of 18 years she had often had to clear away something low down in her throat and had said that she would die from consumption on account of a feeling low down in the windpipe She now complained of constant short hacking cough, loss of smell, indifferent taste, and a very slight discharge from the nostrils There was no history of a foreign body, no dyspnœa or expectoration, and the general health was satisfactory On examination no atrophic changes were found in the nose, pharynx, or larynx, in fact nothing abnormal beyond some slight catarrhal trouble and a small crust in the neighbourhood of Luschka's tonsil Nothing being found to account for the short hacking cough the trachea was carefully examined and a number of papillomatous excrescences or crust-like or cretaceous deposits were seen a large one with ragged edges on the right side, another larger mass deeper down, and a number of smaller nodular ones dotted in an annular or crescentic arrangement around the trachea, the colour and appearances changed a little if covered with secretion. The other part of the mucous membrane of the trachea corresponding to the first seven or eight rings was healthy The diagnosis, in Dr Law's opinion, was very uncertain He had thought of papillomatous excrescences, possibly more or less calcified, ozænic incrustations, herpetic crusts, keratosis, and enchondromata and chalky deposits The patient was brought before the members of the Laryngological Society of London at a meeting last May, and in order to emphasise the difficulty of diagnosis Dr Law quoted from the proceedings of the society some of the views expressed Dr E B Waggett was persuaded that there were no crusts, he regarded the excrescences as being of a papillomatous nature. Dr H. Lambert Lack suggested that the growths in the trachea might really be crusts The fact that the appearances had not changed in 24 hours, in Dr Lack's opinion, in no way militated against his view Sir Felix Semon gave a diagnosis of ozænic crusts and was induced to take this view by the co existence of crusts in the naso-pharynx, and he saw the patient again a month later and confirmed his previous diagnosis of ozænic crusts

Mr T **MARK HOVELL** (London) expressed the view that the growths were papillomata and perhaps associated with changes in some of the adjacent lymphatic glands

Dr W **JOBSON HORNE** (London) had failed to see any crusts and considered that if they had been present there must be some underlying cause for their formation He thought that the diagnosis rested between three conditions—cartilaginous excrescences from the rings of the trachea, calcareous deposits, and papillomata. The appearances in the mirror reminded him of specimens which he had seen of spicules and nodules, composed of hyaline cartilage, projecting from the lower rings of the trachea. He had seen two such specimens abroad, but knew of only one in London and that was in the museum of St. Bartholomew's Hospital, and was the one to which he had drawn Dr Law's attention.

Sir **FELIX SEMON** (London) attributed the appearances to the presence of ozænic crusts in the trachea.

Dr J **MACINTYRE** (Glasgow) considered that perhaps an examination with the x rays might have been of some assistance in arriving at a diagnosis

Dr P **MCBRIDE** (Edinburgh) thought that the condition was due to chalky deposits in the trachea.

Professor **KILLIAN** (Freiburg) was of the opinion that the arrangement and appearances of the growth suggested horny growths springing from the rings of the trachea in its lower part.

Dr **LAW**, in thanking the members of the section for the great interest that they had taken in his case, said that the appearance in the trachea differred from a specimen which Dr Horne had shown him of papillomata in the trachea, but in some respects it resembled the specimen in the museum of St. Bartholomew's Hospital He could not agree with Sir Felix Semon's opinion of crusts, although at the first examination in London there was a much greater appearance of crusts than subsequently Professor Killian had kindly offered to examine the case with the bronchoscope, which would probably lead to an accurate diagnosis, or the use of the probe would differentiate between crusts, papillomatous excrescences, or calcareous deposits, in the meantime he would strongly speak in favour of calcareous deposits (or at least of excrescences which had undergone calcification) He took this view on account of the large number of disseminated white nodules which had not changed in appearance whilst under observation for four months

Professor **KILLIAN** afterwards examined the patient's trachea by direct endoscopy with the bronchoscope, and the excrescences were seen and upon being touched with a probe were found to be of bony hardness

FRIDAY, AUGUST 1ST

Dr **L. GRÜNWALD** (Munich) contributed a paper on

The Present State of the "Ozæna" Question.

He said that it was not easy to speak about "ozæna," for there were nearly as many definitions of this term as there were authors He did not acknowledge ozæna as a disease *sui generis*, but accepted the term for a condition of badly smelling pus in wide nasal passages, and this, the most prominent feature, and its explanation formed the subject of his remarks Speaking first concerning the origin of the secretion he said that if properly examined the secretion of all cases of ozæna would be found to arise from focal disease, where one failed to find it there was not an absence of foci, but they were too obscure to be easily detected He considered that the reservation made, for example, by Hajek, that the focal disease might be only secondary to the general mucous inflammation was quite artificial and had derived no support from Wertheim's 360 necropsies with 95 cases of disease of the accessory cavities. Hajek himself weakened this objection by saying that he had seen cases in a very early state of disease (half a year or so after its commencement) where the secretion could already be proved to be due to focal suppuration. But this statement, he said would not explain why the secretion in a certain number of cases of focal diseases assumed that peculiar form which was commonly called ozæna" From whatever place the secretion might arise it was not to be denied that under certain conditions or in certain forms it might be caused by certain and specific infection (just as specific infection was compatible alike with general and with focal inflammation). And thus they had the attempt to give them etiological factors of general value by proving the presence of specific bacilli. In this respect they had first the bacillus ozænæ of Lœwenberg then the bacillus mucosus of Abel and latterly the cocco-bacillus fetidus of Perez, each of which was said to be the cause of ozæna. But none of these had fulfilled the exigencies of a real pathogenesis—namely that they produced the disease in question in all its forms. The first produced neither crusts nor atrophy the second no atrophy and the third neither crusts nor fœtor Interesting though the investigations of Perez of Buenos Ayres into the correlation between dogs' noses and human infection might be their correctness in European circumstances still required proof and did not seem probable when they considered the enormous number of dogs and the rarity of ozæna in Bavaria as opposed to the scarcity of dogs and the frequency of ozæna in Northern Germany Nevertheless bacteriological researches had brought to notice a very curious circumstance—that the bacillus of Abel produced in cultures a gelatinous tough mass As this bacillus was found principally beneath the true crusts in the tenacious mucus adhering to the mucous membrane it appeared to have a specific relation to ozæna, causing that tough and sticky character of the secretion. Further it was not impossible that altered secretion might produce a fluid of more serous character the coagulation of which might possess greater adherent powers. But this was only a hypothesis, which was not proved even by Schonemann's discovery of degenerated Bowman's glands, for degenerations of the same source would be found in hypertrophied turbinated bodies. This toughness of the secretion would cause it to become fixed in the nose long enough to become putrid and to produce the fœtid smell which was met with also in all other forms of putrefaction of moist masses The assumption made by some rhinologists that this smell was specific had been objected to by others who were zealous defenders of the ozæna theory—namely M. Schmidt Moll and others As to other theories on the etiology of ozæna Hopmann, Siebenmann Gerber and Cholewa-Cordes all considered the atrophy as the primary source of all the other phenomena. But it would be difficult to state a reason why the atrophy of the whole tissue or that of the mucous membrane alone should produce a secretion thus altered without having regard to the unlikeliness of an increased secretion being due to an atrophied membrane in which even the secreting glands had undergone destruction. Moreover all these theories did not discriminate between congenital wideness of the nose and acquired atrophy the occurrence of the former alone being proved by the fact that wide noses were found without the least discharge. If a suppurative process became established in such a nose it found conditions favourable to the establishment of ozæna, as the discharges were likely to be retained long enough to become putrid Even from Cholewa-Cordes's researches it followed that atrophy of the mucous membrane at least, was not the cause, but the consequence of the altered secretion due to the compression and irritation caused by the adherent and putrid crust As to treatment, there was a long series of remedies recommended and most of them had found their well-deserved fate others could produce a perceptible improvement in many if not in all cases It was true that only radical focal treatment had up to now been able to do away with all secretion but it could not be denied that imperfect focal treatment as well as general treatment of the mucous membrane could in some cases alter the whole condition so far that the troubles disappeared. This seemed a strong objection against the statement that the disease was always due to a focal affection, he had never denied but on the contrary affirmed that a great many other factors were required to change the focal secretion into that peculiar to ozæna. If these factors were abolished even without removing all secretion, there would be in favourable cases apparent recovery which practically might approach to a cure. Considering the very great difficulties of radical treatment of focal suppurations in many cases, and especially in disease of the maxillary sinus it would in each single case be a question for consideration whether to take the uncertain way of relief by general measures or the more certain but troublesome one of radical cure by treatment of the focal disease.

OTOLOGY

WEDNESDAY JULY 30TH

The PRESIDENT (Dr W MILLIGAN of Manchester) in opening the proceedings of the section spoke of the need for increasing the teaching of otology and aural surgery with a view of curtailing the amount of ear disease more particularly due to the exanthemata. He expressed the hope that house surgeons would be required to produce certificates of experience in aural surgery before undertaking their duties.

A discussion was held on the Aims and Limitations of Intra nasal Surgical Procedures in the Treatment of Chronic Non-suppurative Middle-ear Disease

Dr J DUNDAS GRANT (London) read a paper on

Cholesteatoma of the Middle Ear

In this communication attention was drawn to the occasional occurrence of spontaneous cure of cholesteatoma of the middle ear the contents finding their way out by causing erosion of the outer wall of the attic and the antero-inferior wall of the antrum leaving such an opening as resulted from a well performed radical mastoid operation as devised by Stacke. Dr Dundas Grant considered that in well marked cases of cholesteatoma when a radical operation was performed and a large cavity was found to be filled with cholesteatomatous masses and lined by a homogeneous membrane, the operator might with economy to the patient's time and tissues leave that membrane *in situ* simply scraping out the contents and sterilising the lining with alcohol. It was understood of course, that by the operation the antrum the attic, the tympanum and the external meatus were thrown into one large cavity In several well marked cases he had found that this practice was followed by speedy subsidence of the discharge and satisfactory after results. The mode of formation of cholesteatoma was described the stages being ulceration of the walls of the cavity followed by granulation, then under favourable circumstances the squamous epithelium from the outer surface of the tympanic membrane and wall of the meatus grew inwards through the perforation in the membrana tympani and proliferated over the granulating surfaces just as in the case of an ulcer on the surface of the body In some cases this extended over the whole of the inner surface of the cavity which was then lined with epidermoid epithelium. Under the influence of moisture or inflammation a process analogous to dermatitis took place resulting in desquamation and the gradual accumulation of layers of epithelium those in the centre broke down and as the mass increased the resulting pressure induced erosion of the surrounding bone sometimes, unfortunately towards the lateral sinus and cranial cavity but in lucky cases towards the external auditory meatus. In cases of disease of the petrous bone in which on radical operation there was found to be only a small cavity Dr Dundas Grant thought that healing might be allowed to take place by means of cicatrisation on the surface of the granulations—the old method. When however the cavity was at all considerable in size and not lined with "cholesteatoma membrane" he held that there was no mode of treatment at all to approach in excellence the method of skin-grafting perfected by Mr C A Ballance In case of a cavity completely lined by pearly membrane he advocated the retention of this membrane and its sterilisation by means of alcohol.

Dr URBAN PRITCHARD (London) said that in his opinion the enlargement of the antrum and mastoid cells in a typical case of cholesteatoma was chiefly due to pressure and not to ulceration of the bone, as was the case in ordinary mastoid disease. This was proved by the hardness and smoothness of the bony walls of the cavity which was moreover lined by a thin altered mucous membrane At the same time he agreed that there were always some spots of ulceration to be found

FRIDAY, AUGUST 1ST

Mr C A. **Ballance** (London) and Mr **Hugh E Jones** (Liverpool) opened a discussion on

The Indications for and against Ligation of the Internal Jugular Vein in Cases of Otitic Pyosepticœmia

Mr Ballance in summarising his conclusions pointed out that the surgeon from his examination of the case must, if possible, come to a clear determination as to the condition from which the patient was suffering—whether from acute systemic infection or from systemic disturbance depending upon a local process He considered that operation upon the vein was indicated in the following circumstances (1) in acute pyæmia and in acute septicæmia whether the sinus was occupied by clot or fluid blood, (2) if the sinus wall was gangrenous or its contents were putrefying, unless it was perfectly clear that on both sides of the area of inflammation the lumen of the sinus was completely blocked by non infected thrombi, (3) if it was proved, or even suspected, that the blood of the jugular bulb was in part or wholly clotted, and (4) if the jugular vein was thrombosed. When it had been decided to deal with the vein before beginning to operate the operation on the vein should precede that on the temporal bone, and when the operation on the vein was first decided upon during the course of the temporal bone operation it should forthwith be carried through without waiting for the completion of the operation on the sinus region

Mr **Hugh Jones** in his paper arrived at the following conclusions 1 Where the clot in the sinus was firm at both ends, though broken down in the middle, and there was little or no cord in the neck, it was sufficient to remove so much of the clot as appeared to be undergoing disintegration and to treat the sinus as an open wound. 2. Where there was no cord in the neck, but on exploration the sinus was found to be permeable though obviously infected, whether lung complications existed or not, the surgeon should obliterate the sinus and tie and divide the vein 3 Where the sinus had been dealt with but the vein had not been tied and the pyæmic symptoms continued or recurred it was necessary to consider carefully in which direction in the sinus the extension was occurring (*a*) If it was occurring towards the torcular, whilst the bulbar end continued sound, there was nothing to be gained by tying the vein, (*b*) if the torcular end was sound whilst a cord was forming and spreading down the neck, whether lung complications had set in or not, the vein should be tied and divided

Dr **Dundas Grant**, in continuing the discussion, considered that the vein should be ligated if suppuration was extending in a clot in the jugular or if symptoms of septicæmia persisted after clearing out the sigmoid sinus or if, on opening the sinus, suppuration was found to extend lower down than could be reached The vein need not be ligatured if the broken down clot was bounded in each direction by a margin of firm organising clot. He deprecated ligature of the vein apart from clearance of the sigmoid sinus As evidence of complete thrombosis in the bulb of the jugular he mentioned absence of fluctuation between one finger on the exposed sinus and another on the internal jugular vein

The **President** spoke of the difficulty in the selection of cases for ligation of the vein Tenderness at the apex of the mastoid process indicated inflammation around the walls of the jugular vein and the necessity for the ligation of the vein In his experience those cases in which the jugular had been tied had given favourable results

Dr F **Rohrer** (Zürich) read a paper on the Relation between the Formation of the Auricle of Anthropoid Monkeys and certain Congenital Malformations of the Human Auricle

Dr A. **Bronner** (Bradford) showed

An Apparatus for the Intra tympanic Hot-air Treatment of certain Forms of Catarrh of the Middle Ear

He confined his remarks to a description of the apparatus, which had been made for him with a view of overcoming difficulties in regulating the temperature of the air used The heating power was electricity The hot-air treatment had been found to be of service in certain forms of middle ear catarrh which had baffled other treatment, and on that account Dr Bronner showed the apparatus

Mr T H **Pinder** (Manchester) had observed benefit to be derived from the external use of hot air in some cases of intractable middle ear catarrh

Dr R. C **Elsworth** (Swansea) made a communication entitled,

Remarks on the Anatomy of the Temporal Bone

The particular point dealt with was a cavity situated immediately behind the antrum, this cavity Dr Elsworth had found to be constant in the specimens he had examined and his observations had been confirmed by observers abroad Dr Elsworth exhibited several sections of temporal bones showing the cavity and demonstrated its relations by means of lantern photographs. A vertical section passing backwards and slightly outwards showed from before backwards—tympanum, antrum, and the cavity to which Dr Elsworth suggested giving the name "accessory antrum." The sections also showed the close relationship which the cavity had with the sigmoid sinus A vein had frequently been met with in the cavity and at times led directly into the sinus itself Dr Elsworth commented on the importance of this vein as a factor in spreading infection when the sinus was the site of disease

Dr J. **Kerr Love** (Glasgow) criticised the introduction of a new term into the anatomy of the temporal bone for the description of this particular air cell.

Dr W **Jobson Horne** (London) pointed out how important it was in the operative treatment of disease of the antrum to be aware of these aberrant cells He also agreed that it was as well to curtail as far as possible the nomenclature of the temporal bone, the term "accessory antrum" as suggested by Dr Elsworth was more explicit than was the name "mastoid cell" The vessel met with in this accessory antrum, and described as passing into the sigmoid sinus, reminded Dr Horne of the petro-squamosal sinus which had been carefully investigated by Arthur Cheatle Its pathological importance, especially in childhood, was probably not sufficiently appreciated

Mr **Hugh Jones** considered that the vein to which reference had been made was the petro squamosal sinus.

LARYNGOLOGY AND OTOLOGY

THURSDAY, JULY 31ST

A conjoint discussion was held by these two sections on

The Etiology and Diagnosis of Ethmoidal and Sphenoidal Suppurations

Dr L **Grünwald** (Munich), in opening the discussion, said that the etiology of these two diseases corresponded in general with that of other focal suppurations of the nose, they were acute infectious disorders of general or local origin. The principal factor in the production of a chronic disease from an acute inflammation in this situation was impediment to free discharge The sinuses in question had their openings situated at their deepest and most dependent parts—that was, under the most favourable conditions for drainage. This, however, would be altered by swelling of the adjacent mucous membrane, and to this the ethmoidal bone especially was much exposed Such a swelling might be superadded to a previous acute inflammation of the cells themselves, or it might be the consequence of an inflammation in an adjoining cavity Sphenoidal, and ethmoidal suppurations rarely occurred alone, in most cases they were combined with suppuration of other cavities, or they might occur together Ethmoidal suppuration was found alone more frequently than was sphenoidal, and this statement would be only slightly changed by the consideration of the much greater difficulty of making the diagnosis in the latter affection In his own cases sphenoidal suppuration was combined with ethmoidal disease on the same side in 73 per cent., but in ethmoidal affections the same combination existed in 40 per cent only Chronic sphenoidal disorders were therefore frequently secondary to those of the ethmoidal bone He had seldom met the combination of sphenoidal and maxillary antrum disease though other authors had more frequently seen this The combination of ethmoidal with maxillary suppurations was more common, and although he did not in the least agree with Weil's view, that all obstinate maxillary suppurations depended upon disease of the ethmoidal bone, he agreed that suppuration of the ethmoid alone was frequently diagnosed when only one or other of its cells might be slightly affected whilst the more important and fundamental maxillary inflammation was overlooked. It seemed to be unknown, but he had no doubt that adenoid growths could infect the ethmoidal as well as the sphenoidal cavities directly by their secretion and could prevent by the maintenance of swelling the natural cure by drainage of these cavities when once infected.

Speaking of subjective signs he said in some cases of sphenoidal inflammation no complaint might be made, but in others vertigo pains of occasionally excruciating character on the vertex deeply in the head behind the eyes or by false localisation, in the region of the ears, or not uncommonly in the occiput, were present. But how uncertain subjective signs in general were might be gathered from Schäffer's and his own observations of typical supra-orbital and infra-orbital neuralgia in such cases. These symptoms, unexpected as they might be, were not merely accidental, but were caused by an irritation of the spheno-palatine ganglion, the immediate neighbour of the sphenoidal cavity The thoroughly false view that the causes of pains must be found near their localisation often led to the general mistake as to the frequency of frontal suppuration. Loss of smell frequently accompanied chronic sphenoidal suppurations in consequence of the obstruction to the fissura olfactoria. Ophthalmic troubles such as asthenopia, scotoma, painful irritation of the ophthalmic nerves, and deterioration of writing power as noted by Schäffer were explicable by the neighbourhood of the orbital and the basal nerves Pain was usually more violent in acute inflammation but then it was on account of radiation to more distant regions still more uncertain as a diagnostic sign. The same held good with disease of the ethmoidal bone, only here the troubles were usually more severe than in any other cavity and here more especially those disagreeable complications of constant pain mental depression, and intolerance to nervous excitement might be found. Asthenopia was also frequent, and the pain would often be referred to the region of the eyes. Supra-orbital neuralgia might occur here as well as in frontal empyema, combined with tenderness on pressure. Special to ethmoidal disease was the pain produced on pressing the lachrymal bone, a fact which was examined by the vicinity of the lamina papyracea.

Concerning objective signs Dr Grünwald agreed with Hajek in his division of the ethmoidal bone into cells of the upper and middle meatus, and thus he considered that the old difficulties in settling the places of discharge for anterior middle and posterior cells were removed once for all Cells of the upper meatus as well as the sphenoidal antrum discharged into the recessus spheno-ethmoidalis, and the pus of both cavities would therefore more frequently flow down to the naso-pharynx than would that of any other cavity and would produce the well known *appearance of post-nasal catarrh. When the* pus ran forwards it was nearly always found in the space between the middle turbinated body and the septum Dr Grünwald said that this localisation was not of absolute diagnostic value only a discharge rapidly re-forming after its removal and gushing out would signify its descent from one of the cavities in question The anterior cells emptied themselves into the hiatus semilunaris or into a posterior part of the middle meatus, and their openings might thus be easily mistaken for those of the maxillary and frontal sinuses as the openings of all these cavities were very close together One diagnostic sign to which he drew special attention was the purulent and even fœtid character of the secretion in contrast with the more frequently muco-purulent or mucoid character of that from the maxillary antrum Speaking of the secondary disorders of the mucous membrane, he said that they were generally of less significance Polypoid degeneration of the middle tubinated body was equally significant of suppuration of the anterior labyrinth of the larger cavities. Isolated inflammations of the labyrinth hardly ever occurred without the production of polypi, the mucous membrane of this region being particularly prone to œdematous degeneration. When in cases where no suppuration might have been apparent previously multiple polypi in the region of the middle turbinated bodies were torn and not cut off so that some bone was removed with them, it often happened that œdematous growths within the *opened cells or holes of the middle turbinates* would be observed—a true sign of previous ethmoidal inflammation the secretion in these cases was scanty on account of the advanced degeneration of the glands and vessels, so that it was practically hidden behind the tumours In the same manner a production of polypi would often persist for a long time after the cessation of the ethmoidal suppuration. The rhinoscopic appearances in sphenoidal suppurations alone scarcely differed from the normal, those of ethmoidal inflammation varied according to the different pathological forms of labyrinthine disease. The closed or ethmoidal empyema proper produced an expansion of the affected part of the labyrinth or its appendages (the bulla ethmoidalis or middle turbinal) and gave the aspect of a bony bladder within or by the side of the concha. Latent open suppuration might exist without any visible effect, but in the majority of cases there were smaller or larger hyperplastic growths on the middle turbinal and very often the participation of the deeper tissues became evident by the appearance of a considerable extension of a concha, the surface of which was covered with granulations or polypoid degenerations, so that it occasionally appeared double Distinct though these appearances might be, the diagnosis would never be sure until the presence of pus within the cavities was proved. For this purpose the probe was used. Roughness or caries of the bone or the presence of the soft or loose necrotic particles might be found but all these signs were of but secondary value. As to the position which the probe had to occupy in the sphenoidal cavity and the distance of this cavity from the anterior nares, he said that it was impossible to give absolute measures of distances and heights of the ostium, as these differed too much to allow of any certainty In general the ostium was situated opposite to the posterior end of the upper turbinated body and that the probe was in the proper position would become evident only by the impossibility of moving it downwards. The same was true as regarded the control of its position in the ethmoidal cells, in contradistinction to the recessus spheno-ethmoidalis (for cells of the upper meatus) and to the middle meatus (for anterior cells) The former could be reached from the recessus by a probe with a lateral bend the latter from the middle meatus on both sides. A division of the sphenoidal antrum by a vertical or horizontal septum could thus be recognised by the probe and had a very *great practical* value. *Whether this deformity* was caused through the formation of a septum or by the dislocation of a posterior ethmoidal cell could scarcely be made out in the living subject. Congenital abnormalities in the cavity might render their exploration quite impossible. For the diagnosis of disease of adjoining cavities the application of a temporary tamponade was of the greatest value. In some cases to get sufficient room it was necessary to make a resection of the anterior part of the middle turbinal and in ethmoidal suppurations this preliminary operation could rarely be avoided for proper treatment In sphenoidal suppuration this operation was only exceptionally demanded. Whatever cavity might be thus explored suppuration in it would not be decided unless pus was running down along the probe or could be drawn or washed out by a cannula. The seriousness of the disorder and the further indications for its treatment would become evident by testing the state of the bone and soft parts with the probe. Diagnosis would naturally be much facilitated by some of the signs thus obtained especially when the probe got immediately through the mucous tissue into cavities by the feeling of loose bone, &c. In doubtful cases the examination of both sides of the nose should never be forgotten, as it was possible that an empyema of one ethmoidal labyrinth might discharge on the other side through a septal perforation. Lastly a warning was given against wrongly diagnosing ethmoidal and sphenoidal suppuration when a *malignant growth was really present* the early stages of which might simulate suppuration with inflammatory hypertrophies. Only great experience and attention to the whole course of the disease could prevent such an error

---

DERMATOLOGY

THURSDAY JULY 31ST

Professor T C. GILCHRIST (Baltimore) read a paper on

Blastomycetic Dermatitis

It was preceded by a lantern demonstration of a large number of slides illustrating the occurrence and the life-history of the blastomyces and the organism of so-called protozoic dermatitis" Professor Gilchrist commenced by describing a case which had been recently under his care The patient was a negro (and this point was noteworthy because the disease had not previously been described as occurring in a negro) in whom there was a marked family history of phthisis. For the last six years he had been in the penitentiary for manslaughter and evidently the disease had been contracted there. About two years ago a small sore appeared on the abdomen; it caused no pain It enlarged gradually until it formed an ulcer measuring nine centimetres by 16 centimetres and a second ulcer was also present nearly as large. The lesion was evidently superficial, for the skin could be moved over the deeper parts, the edges were studded with minute abscesses For one month there had been swellings in the groin and right axilla. The temperature varied, rising as high as 101 5° F The lungs were unaffected The blastomyces was present and easily found. Rapid improvement occurred under large doses of potassium iodide (100 grains three times a day) Up to the present 33 cases of blastomycosis of the skin had been described (22 in men and 11 in women) and five cases of protozoic dermatitis Of all these only two had been seen in Europe, and of these one came from America It might therefore be looked upon as an American disease Blastomycosis was a chronic infectious disease of the skin occurring between the ages of 20 and 60 years It began as a papule, then forming a wartlike lesion which gradually spread It was superficial and painless and tended to heal, forming scars The edge of the patches was well defined and raised, and contained many minute abscesses The disease was auto-inoculable, for the patches were generally multiple. The blastomyces measured about 12 μ in diameter, it was double-contoured, and it contained no nucleus In most cases there was no glandular enlargement and only two cases had proved fatal. Protozoic dermatitis resembled the blastomycetic dermatitis in many ways, but the organism increased in number by sporulation instead of by budding and for this reason it had been thought that the organism was a protozoon, but there were so many points of resemblance between the two diseases that in all probability the two were produced by organisms which were closely allied

The PRESIDENT (Dr H A. G BROOKE of Manchester) said that he had derived much pleasure from the paper and demonstration and was proud that Professor Gilchrist was an *alumnus* of the Owens College —A formal vote of thanks to Professor Gilchrist for his paper was moved by Mr MALCOLM MORRIS (London), seconded by Dr H. RADCLIFFE CROCKER (London), and carried unanimously

A paper was communicated by Dr J H. SEQUEIRA (London) and Mr H. BALEAN (London) on

Lupus Erythematosus

It was based on the observation of 71 cases, of whom only 11 were males The disease began early eight cases commencing between 11 and 15 years of age In 34 cases there was a family history of tuberculosis and two cases of lupus erythematosus occurred in one family Tuberculosis was present in 18 cases There was a history of scarlet fever in five cases Two forms of the disease occurred, the discoid and the disseminated, but these varieties merged into one another In 11 cases the disease commenced in multiple small foci. Local irritation appeared to be an exciting cause, for instance, one case developed after the application of a poultice. Out of 27 cases in which the urine had been examined albuminuria was present in seven, and it was especially frequent in the disseminated cases The disease appeared to affect special vaso motor areas The authors concluded that lupus erythematosus was not bacterial in origin but was caused by a toxin circulating in the blood and acting on the capillary vessels They thought that it was not possible to say that the toxin was the product of tuberculosis

Dr CROCKER mentioned that he had seen several cases of the disease in which albuminuria was present.

Professor GILCHRIST pointed out that they must not too readily conclude that a disease was due to a toxin because it was not possible to find a micro-organism in it. It had been shown that there were microbes sufficiently small to pass through porcelain filters.

Dr GRAHAM LITTLE (London) thought that a great argument against lupus erythematosus being due to a toxin from tuberculosis was to be found in the fact that the disease was certainly rare in the Brompton Hospital for Consumption

Dr J M H MACLEOD (London) read a paper on

The Histological Changes in the Skin after Light Treatment

This paper was illustrated by some excellent diagrams In all the cases examined the typical reaction had been present. The first change had been the occurrence of an œdema round the margin of the tubercle This was followed by an œdematous destruction of the fibrous elements present and the plasma cells became vacuolated and the nuclei disappeared The giant cells were attacked in the same way An important point was that the cells showed a definite tendency to become elongated and to form fibres and thus lead to cicatrisation

The section then visited the Manchester and Salford Hospital for Diseases of the Skin, where the President and Dr G H. Lancashire demonstrated the instruments employed and the mode of application. There were one large Finsen lamp for four patients, two small lamps, two apparatus for the production of x rays, and a high frequency current apparatus. Many cases, chiefly lupus, were seen which had been under treatment The installation was very complete and up to date

FRIDAY, AUGUST 1ST

At the commencement of the meeting the PRESIDENT referred to the great loss which dermatology had sustained in the recent death of Mr W Dale James of Sheffield who had borne many afflictions with great fortitude and resignation

Psoriasis

A discussion on psoriasis was introduced by Mr MALCOLM MORRIS (London) He said that of psoriasis it might truly be said that its causation was unknown, its pathology was obscure, and its treatment was unsatisfactory A convenient starting-point for a summary of the progress made in recent years presented itself in the discussion on psoriasis which took place at the annual meeting of the British Medical Association in 1893 On that occasion Dr H Radcliffe Crocker suggested that the disease might be the outcome of two factors, the primary lesion being vaso motor in character and a parasite being a secondary but necessary agent Mr J Peeke Richards, while medical officer of the Hanwell Lunatic Asylum, observed that psoriasis occurred much more frequently in cases of perverted nervous action, such as delusional insanity, than in cases of lessened nervous force, as dementia, while Dr J J Pringle expressed himself in favour of the trophoneurotic theory of its origin On the other hand, Dr Norman Walker was inclined to think that it was parasitic. As to the treatment, the speakers expressed views almost equally divergent. Six years later the distinguished President, Dr Brooke, in the most lucid and complete monograph on psoriasis that existed in their language, confessed that, "notwithstanding researches in every direction—social, statistical, chemical, microscopical, and bacteriological—the cause of psoriasis is still unknown" Reviewing the various opinions on the subject he grouped the hypotheses under three headings—namely, humoral, neuropathic, and microbic It was obvious that there were serious objections to all three hypotheses taken singly The humoral theory postulated that all sufferers from psoriasis were the subjects of gout, rheumatism, or some other dyscrasia, but clinical experience showed that this was true only of a small minority The neuropathic theory also rested on a relatively slender foundation of facts, and the parasitic theory was also open to the objection that it had so far been impossible to fix the responsibility for the disease on any particular micro-organism, and attempts at artificial inoculation had failed As to the pathology of psoriasis there was almost as much discrepancy of opinion as there was in regard to its causation and observers were not agreed even as to the primary lesions. All the more recent writers recognised that there were present (1) an increased production of epithelium, (2) an abnormality in the process of cornification of the epithelium, and (3) a dilatation of the blood vessels The most important recent contribution to the pathology of psoriasis had been by Dr W J Munro He believed that the earliest lesion was the formation of a small "dry" abscess at the surface of the horny layer and he looked upon the hyperkeratosis as a local defensive process against the abscess These researches, however, threw no light on the origin of the disease With regard to the pathological question generally it might be said that the opinions of dermatologists were at present pretty equally divided between the neuropathic and the parasitic theories These theories were not mutually exclusive, for the two factors might coöperate. It was conceivable that the true explanation of the origin and nature of the disease was to be found in a combination of causes, local and general Thus psoriasis might begin as a local response to irritation set up by the presence of a local agent or condition and constitutional disturbance caused by the production of toxins and, lastly nervous disorders might become developed as a consequence of profound toxæmia. He could not help thinking that if the primary etiological factor were a parasite it would not have eluded the persevering search that had been made for it in lesions so superficial as those of psoriasis The development of psoriasis on the site of vaccination which had sometimes been noted, and of which he had himself seen several cases, might, in view of the acknowledged failure of inoculation experiments be explained by the local irritation producing the condition of neuro-vascular disturbance necessary for the production of the specific toxin. If the poison were introduced with the vaccine lymph or into the wound afterwards vaccination would more often be the starting point of psoriasis than it was. Heredity probably did play some part if not in the actual genesis of the disease at least in the production of a type of skin favourable for its development. The greater frequency of psoriasis in Europe, and especially northern Europe, compared with America seemed to show that climate had some etiological influence. It had long been taught by French dermatologists that there was a relation between osteo-arthritis and certain other joint affections and psoriasis. Mr Morris had seen several cases in which joint affections existed concurrently with psoriasis There were several types of psoriasis (1) there was the simple uncomplicated form with occasional outbursts of activity seen in young persons without any sign of impaired health (2) there was the acute rapidly spreading form associated with headache, asthma, and other nervous symptoms (3) there was a form occurring in connexion with osteo-arthritis associated with severe constitutional disturbance (4) there was psoriasis which passed into pityriasis rubra and (5) there was a simple but atypical form which resembled seborrhœa. As a general rule no internal medication should be employed except in response to a definite constitutional indication. Arsenic was worse than useless in acute cases. When hyperæmia or active inflammation was present antimony was called for As to local treatment, bactericides applied to the affected parts gave the best results. If there was no hyperæmia the most efficacious was unquestionably chrysarobin. Tar in the form of liquor carbonis and mercurial ointments of moderate strength were also serviceable. In severe forms associated with joint affections arsenic internally was useful In one very severe case an exclusively meat diet, washed down by copious draughts of hot water proved very effective. In the type of psoriasis in which there was a tendency to the development of pityriasis rubra all irritating remedies must be at once discontinued Very weak preparations of tar were useful and if the attack was severe the patient must be kept in bed. In psoriasis of the seborrhœic type the best application was sulphur In slight cases of psoriasis complete destruction of the early lesions should be arrived at and the best security against relapses was the complete removal of all remnants of the disease

Dr LESLIE ROBERTS (Liverpool) expressed the opinion that psoriasis was not microbic but due to a poison He drew attention to the great resemblance of its action to that of arsenic. He was inclined to think that the disease was associated with the abnormal action of some gland, probably the thyroid gland. The course of the disease was probably modified by seborrhœa. He had not much confidence in internal treatment, and of internal applications he considered chrysarobin to be the best. Inunction of simple ointments, continued for a long time after the apparent cure of the disease prevented recurrence.

Mr GEORGE PERNET (London) considered the disease to be parasitic. For all ordinary cases he employed the internal administration of salicin which had been first advocated by Dr Radcliffe Crocker Arsenic was only to be employed in chronic and resistent forms. He had known a case treated by the exclusively meat diet which grew worse

Dr A. EDDOWES (London) looked upon the disease as microbic. He thought there were many drawbacks to the use of chrysarobin and he considered that painting the patches with liquor carbonis detergens was the most effective local treatment.

Professor GILCHRIST had examined many early lesions of psoriasis but he had never seen "dry" abscesses in the horny layer He had seen much benefit from the administration of 40 grains of potassium iodide three times a day Salicylic acid was a very effective local application. Treatment should be continued for from 12 to 18 months after apparent cure

Dr ARTHUR WHITFIELD (London) had found nothing characteristic in the histology of psoriasis. He did not believe in dry abscesses, for leucocytes could not wander in a dry substance. These so-called 'dry abscesses occurred in lichen planus and other scaly lesions. He did not say that the disease was parasitic, but the great tendency to recur if any patches were left uncured was a distinct point in favour of a microbic origin.

Mr WILLMOTT EVANS (London) wished to endorse what Mr Pernet had said as to the great value of Dr Crocker's treatment by salicin. All the members of the salicylic acid group were useful but salicin was probably the best. For persistent patches of psoriasis he thought the best application was an ointment of chrysarobin 50 per cent. with 25 per cent. of salicylic acid of course this should only be applied over a small area.

Dr NORMAN WALKER (Edinburgh) said that he had seen good results from the administration of extract of thyroid gland in combination with arsenic.

The PRESIDENT said that the variety of opinions as to the cause of psoriasis reminded him of the theories of the etiology of phthisis before the discovery of the tubercle bacillus.

Seborrhœa

Dr NORMAN WALKER read a paper on the above subject He pointed out that there was a want of agreement as to what was meant by seborrhœa some confining the term to the dry form and some to seborrhœa oleosa. He thought that in this country the name was chiefly used for the dry form and that when it was intended to speak of the oily variety the adjective oleosa" was appended. The scales in seborrhœa were not dried secretion but were derived from the epidermis It must be recognised that the sweat glands secreted a fatty" fluid With regard to seborrhœa corporis he thought that its relation to seborrhœa capitis might be very aptly compared to the relation subsisting between tinea capitis and tinea circinata. For instance, while on the body a tinea might form a definite inflammatory ring on the scalp it formed dry scales. The amount of dermatitis present in seborrhœa varied greatly Was seborrhœa oleosa the same disease as seborrhœa sicca? It was very difficult to speak with certainty It seemed certain that with the oily form baldness was not so common but the hair tended to turn grey

The PRESIDENT said that it was generally agreed that seborrhœa was certainly microbic in origin and that fact gave them a definite basis from which to start.

Dr T COLCOTT FOX (London) thought that Sabouraud had done great service in this matter and that endless confusion would arise unless they distinguished the oily from the dry form. In the oily form the oil could be definitely seen to exude from the pilo-sebaceous orifices.

Dr LESLIE ROBERTS pointed out that fat was excreted by the skin in two ways In the case of the sweat glands it was a pure secretion, but in the case of the sebaceous glands it was an exfoliation He thought that oleorrhœa" would be a useful term for excessive fatty secretion from the skin.

Professor GILCHRIST referred to some researches of his on a bacillus in acne vulgaris and its relation to Sabouraud's bacillus.

Dr WHITFIELD pointed out that the patulous glands on the nose were not necessarily the openings of hair follicles only and he considered that they might be looked upon as cloacal apertures of hair follicles, sebaceous glands, and sweat glands.

Mr. PERNET read a paper on

The Tumours of Xeroderma Pigmentosum

The case was sent to Dr Crocker at University College Hospital in September 1901 The child was eight years old and had been first deeply freckled in 1895 The condition had been steadily getting worse and the face was the part most affected being the seat of a general desquamating dermatitis and thickly studded with pigmentary macules On the face there were two growths a small one just below the left lower eyelid and a large flattened sessile mass between the eyes of about the size of half-a-crown Its surface was irregular and crusted. The growths were removed in the country and the larger one was examined. Masses of epithelial cells pervaded the corium but no connexion could be traced between these cells and the surface epithelium There were indications favourable to the idea that the new growth was derived from hair follicles. Mr Pernet referred to other descriptions of tumours occurring in xeroderma pigmentosum.

INDUSTRIAL HYGIENE AND DISEASES OF OCCUPATION

THURSDAY, JULY 31ST

Dr C A. GREAVES (Derby) read a paper opening a discussion on

The Granting of Certificates of Fitness to Children and Young Persons employed in Factories and Workshops

He stated that he considered that it would be superfluous to demonstrate the propriety of the policy of medical certification but for the probability that outsiders might note the proceedings of the section and the fact that in 1891 an attempt to abolish certifying originated chiefly in Lancashire. He said that he would therefore note briefly the grounds on which this limitation of free trade in labour rested as a preventive of injury to urban workers Adverting shortly to the course of factory legislation, from the Apprentices' Act, to the comprehensive enactment of 1901 and the important part played by Lord Shaftesbury in the reform of a system under which children even at the age of five years could, prior to this legislation be subjected to industrial slavery, he said that it was something of a shock to him to recall that in 1868 (when he entered on the certifying function) children of the age of eight years could work half time in mills Since then the hours had been shortened, the ages raised, the work regulated, and education enforced, while the half-time system was almost obsolete Parents and public opinion were more enlightened, but if inspection was withdrawn the helpless would still go to the wall The importance of medical knowlege was formerly recognised by the appointment of Dr Robert Baker with Mr Alexander Redgrave as conjoint chief inspectors of factories, and then after an interval of lay superintendence the selection of Dr B A. Whitelegge opened a new vista to preventive medicine. Why, then, was medical inspection essential for the protection of the workers? It was impossible for the present staff of inspectors, with their many duties and wide districts, to give adequate supervision to the multitude of young hands—their visits were necessarily rare while those of the medical man were frequent. The objects of requiring certificates might be classified as (1) avoidance of injury to the individual as to health, growth, or bodily capacity, (2) protection of the fellow workers of whatever age or sex, (3) preserving legality and thus protecting the employer, and (4) checking unfair competition and so protecting the conscientious from the unscrupulous manufacturer The protection of the individual on the one hand and the fellow workers on the other could not be secured without medical knowledge and judgment. In considering reasons for refusal of certificate the nature of the work was always considered, and it was satisfactory to note that the Act of 1901 allowed the certificate to be qualified by conditions as to the work and gave the surgeon power to inspect the processes Amongst the grounds for rejection that might be specified debility, malnutrition, deformity, rickets, joint disease, spinal curvature, sore eyelids, and distance from home chiefly concerned the young person examined, abscesses, ulcers, bone sinuses, scrofula, phthisis, ophthalmia, bad sight, deafness, and imbecility might also involve injury to the fellow workers, while the fellow workers were also in view in the case of eruptive fevers scarlatinal desquamation, mumps, whooping-cough, vermin and dirt, ringworm and other skin diseases, and non vaccination. When in 1891 the opponents of the medical examination alleged that there were few rejections recorded he (Dr Greaves) made a return of 2000 in 23 years in Derby alone Their frequency had diminished but it was undoubtedly still necessary to safeguard the helpless in the struggle for wealth. Referring to the desirability of requiring certification in workshops, he remarked that the absence of steam or other mechanical power was an inconclusive index of healthy employment and the Secretary of State had power to require medical examination in any class of workshops Section 65 a permissive clause allowing workshop owners to obtain medical certificates "if they think fit," was a dead letter as it involved some pecuniary outlay The question as to the practicability of fixing a standard of physical fitness for work must be answered in the negative, neither height, weight, nor muscular strength would be satisfactory, and different employment would require different standards. Fitness for specified work could only be properly decided by an examiner with medical knowledge and experience, an independent position, and moderate sagacity In conclusion, Dr Greaves entered an energetic protest against the statutory provision which in certain cases enabled the employer to demand a certificate of fitness from the medical man at his own consulting room and to tender 6*d* as a fee for this medical service

Professor C J WRIGHT (Leeds) said that he looked for an extension of the use of certifying surgeons In Leeds he saw hardly anything of half time labour The raising of the age limit had been very beneficial, not only as regarded half timers but also as regarded young persons under 14 years of age He looked on the preventive aspect of the Act as the most useful. He asked whether it was for the public good that a certifying surgeon should receive such poor remuneration for making his examination.

Dr A. CAMPBELL (Dundee) contributed a paper with special reference to the system of half time employment. Referring to the recent legislative changes under which a young person could work full time at 13 years of age after having procured an exemption certificate from the school board, Dr Campbell said that his experience was that however popular this change in the law might be it was not favourable to the health of either the children or the young persons He thought that if by an Act of Parliament all young persons and children could be kept at school till they attained 15 years of age much might be said in its favour Most educationists, and especially those who had had experience of both systems, agreed that the half day system was the better and more natural one. From personal experience and careful watching during many years he was convinced that children improved steadily in their health and strength under the half-time system. By admitting them into half-time they were taken away from the long hours in the day school which were probably the chief cause of their white faces and wearied looks, and it insured their being regularly fed and gave them sufficient time for play The diminution in the number of half timers in recent years could be accounted for by the way in which they had been treated In schools they were looked upon as of a different caste and sympathised with and the system was spoken against by a sentimental public who had not taken the trouble to inquire into the whole bearing of the case The great value of the certificates of fitness as given by certifying surgeons after professional and personal examination as to health and fitness, and the power and influence which had been exercised in safeguarding the young persons and children from being worked in factories when unfit, had long been satisfactorily proved. This certification being so necessary in factories it was in many respects more so in certain classes of workshops, and so long as certifying surgeons had not the same power conferred upon them of examining young persons and children employed in workshops as they had those employed in factories only a portion of the young persons and children were being cared for and protected as they ought to be.

Dr J HOLMES (Radcliffe) agreed that the extension of the system of examining children was advisable

Dr T F YOUNG (Bootle), Mr C W THORP (Todmorden), and Mr H. HAMMOND SMITH (Uxbridge) also joined in the discussion.

FRIDAY, AUGUST 1ST

Dr JAMES NIVEN (Manchester), in opening a discussion on

The Relation of Phthisis to Factory and Workshop Conditions,

said that a study of the supplement to the Fifty-fifth Annual Report of the Registrar General revealed that in 19 out of 44 counties, two of the 19 being coal mining counties and the rest chiefly agricultural, the death rate for females exceeded that for males This was the relation which would be expected were infection chiefly to occur in the house In nearly every large town the death rate from phthisis for males exceeded that for females—in many considerably When the occupational death rate from phthisis for males was analysed by using the figures given by Dr Tatham in his Analysis of Occupational Death rates, Part II. of the above mentioned Supplement, it was perceived that the high occupational death rate from phthisis for males in large towns was due to a variety of causes, amongst which the habits of particular classes as regarded intemperance and their circumstances and place of abode were the most considerable. The very great influence of the circumstances and places of abode was well illustrated by the three main statistical divisions of Manchester These factors also entered largely into the relations of phthisis to factories and workshops. There were also many occupations in which the work itself was adequate to produce a high death rate from phthisis, but the occupation might be only partly causal. A predisposition might be produced at the workshops or the infection might take place in the home, in the public house, or in some social place of resort. The measures needed were multiform but it was requisite to consider only the more important. 1. Compulsory notification of all cases of tuberculous phthisis was required so that every operative might be instructed in the precautions needed to protect his fellow workmen and assisted to carry them out efficiently Voluntary notification was almost equally useful however in the poorer parts of the city 2. All spitting in workshops should be prohibited. This was easier to state than to effect, but with a great effort it might be managed The first thing was to bring home to masters and operatives the vital necessity for this measure. Men requiring to spit should carry a pocket spittoon. 3. Increased efforts should be made to secure systematic wet sweeping as far as possible daily in workrooms. The dry sweeping usually practised was liable to do much harm if spitting went on It would be an additional safeguard if the rooms were dredged with a disinfectant, as in the case of wool-sorters under the special regulations. As regarded the lighting of workrooms, it was essential that there should be sufficient light by which to see to cleanse the workrooms in all parts though more than that would be beneficial If lighting must be artificial either electricity should be used or gas If gas was used it should be regarded as essential to have intensified lights in which complete combustion was the case, with reflecting shades and tubes connected so as to carry off the waste gases and aid ventilation. It must be carefully considered what was aimed at by ventilating appliances In schools clearly it was the removal of respiratory impurities, but in workshops it was very often a question whether the removal of dust was not the more important object. It was not easy to see how to deal with the more generally diffused dusts in carding rooms, iron turning marine stores and so forth. Various ideas presented themselves, such as supplying fresh air to the operatives by special tubes and ventilation on the plenum system with removal of the dust-laden atmosphere from below but these did not appear at present to be within the domain of practical politics. It was essential that public houses should be placed under strict legislation in respect of cleanliness and that spitting in public-houses should be prohibited. It was partly in the workshop but to a much larger extent in public-houses that the inhabitants of common lodging houses propagated amongst the industrial classes tuberculous phthisis which made such ravages amongst them Hospital provision was needed at the expense of the rates for the removal of consumptives from crowded homes. But in regard to phthisis directly arising in the course of work he was satisfied that, having regard to occupations generally the two most urgent requirements were the suppression of spitting and the maintenance of strict cleanliness, the workrooms being wet-swept.

Dr G C MCLEARY (Manchester) contributed some remarks on the prevalence of phthisis amongst laundry workers. He said that the conditions of employment were subject to imperfect legislative regulations. The work was often carried on far into the night, Sunday work was not prohibited and persons below 16 years of age might be employed without the certificate of fitness for employment without which no such person might work in a factory The habit of intemperance which was unfortunately common amongst laundresses also weakened the resistance of the tissues to the attack of the tubercle bacillus. Finally there was the risk of infection in the sorting room Phthisis as a disease of comparatively frequent occurrence amongst laundresses was not easy to prove inductively The death registers were of no avail, as it was a common practice in registering the death of a female to mention the occupation, not of the deceased, but of her father or husband This practice was much to be deplored and it was to be hoped that the Registrar General would take steps to institute a system of death registration which would enable statistics to supplement the valuable information already possessed with regard to male occupational mortality by information which would be of almost equal value concerning diseases of occupation in females

Dr ARTHUR RANSOME (Bournemouth) agreed with Dr Niven that the public-house was a great factor in the spread of consumption though he would also include theatres and music halls and possibly places of worship.

Dr W M ROBERTSHAW (Stocksbridge) contributed a paper on Ganister Miners Disease. In discussing this subject he said that it was well to say something about ganister itself. In certain manufacturing processes and especially in those connected with certain Sheffield trades, a heat resisting substance was required which would stand very high temperatures. Such a substance was ganister a hard, close-grained mineral, consisting mainly of silica, which it contained to the extent of 95 per cent. Ganister occurs principally in the South of Yorkshire and more particularly in that part of the Don watershed between Penistone and Sheffield, where it is associated with the lower coal seams. In the mining preparing and manufacturing of this mineral the disease which had been called ganister miners disease or ganister disease was produced. For many years the disease in the Stocksbridge urban district passed unnoticed but the number of deaths occurring amongst the miners at the ganister works drew attention to the condition. Ganister being extremely hard it was impossible to mine it with the pick. It was therefore blasted with dynamite. On being brought to the surface it was crushed in "breakers," and then ground into a powder in which state it was used for lining Bessemer converters, making bricks &c. Two main sets of workmen were affected by the dust—the miner who got the mineral and the surface workman who prepared it and manufactured it into bricks &c. In the mining process a hole was first drilled in which the dynamite was placed. The workmen having retired the dynamite was fired by time fuse and percussion cap Dust which consisted of particles of ganister was produced in boring the hole, and when the shot was fired the whole was disturbed and the place reeked of it. Dust was produced by the breakers and grinders and in that way surface workmen became affected. There had been and still was, a great difference in the certifying of deaths of workers in this industry while the majority of practitioners certified the cause of death as phthisis a few had been more correct and had used the terms fibroid phthisis, pneumonokoniosis " or ganister miners disease. This was important, because unless it was taken into consideration many deaths really due to this condition might be overlooked With regard to the relation of the disease to tuberculous disease Dr Robertshaw was of opinion that the cases might be best classed under three heads: (1) those in which after the fibroid change had damaged the lungs true tuberculous phthisis played the chief part (2) those in which tubercle was found but which was only very secondary to the fibroid disease and (3) those in which there was no tubercle at all the disease being entirely due to the fibroid change brought about by the ganister dust. The majority of cases were found in the last two classes. The following suggestions were likely to do a good deal towards stamping out this scourge. No miner should go into the workings for half an hour after the blasting shot had been fired A limit should be put on the length of time during which a man was permitted to work at any of the dangerous branches of the ganister industry and such improved conditions (such as better ventilation) as obtained at present should be continued and extended.

Dr T WATTS (Hyde), speaking on shuttle threading as a source of infection in phthisis said that it constituted one—if not the greatest—of the dangers of the cotton manufacturing process. The method at present in vogue amongst weavers of threading shuttles in looms consisted in what was popularly known as sucking up the weft which was carried out as follows. When the shuttle ran empty the weaver put a new cop in and the free end of the weft was then drawn through the eye of the shuttle by suction, the shuttle being placed between the weavers lips for the purpose and by means of a forced inspiration this weft was drawn through the eye and unfortunately whatever else was in the shuttle was drawn into the mouth and respiratory passage When it was remembered that a weaver in charge of three looms—which was most usual—performed this little operation on an average once for each loom every five minutes which worked out at 36 times an hour or 360 times during a working day of 10 hours it would readily be seen that any injurious effect, however slight, was very much increased by the number of times that it was repeated If a shuttle taken from a working loom were examined in the cavity of the shuttle, especially about the eyelet, there would be found a quantity of dust and this on examination would be found to consist of "size" and cotton fibres A weaver nearly always used the same looms and consequently the same shuttles, but a weaver suffering from incipient phthisis had frequent break downs and was away from her work, at which times her looms were taken charge of by others whom in this way she might infect What had been said with regard to tubercle applied also to syphilis, diphtheria, lupus, &c, but it was in the risk of tubercle infection that the greatest danger lay His attention had lately been drawn to a simple and effective means of threading a shuttle by means of an indiarubber pump which could be worn secured to the bodice by means of a safety pin. This simple little instrument did away entirely with the objectionable and unhealthy method at present in vogue He had found it difficult to get the older weavers to use it, but children and young persons took readily to it, and every child or young person when first commencing work in a weaving shed ought to be warned by the certifying surgeon at the time of his examination of the dangers of drawing the weft through by means of the mouth and to be trained from the first to some other method of threading the shuttle

---

ETHICS

Friday, August 1st

Sir Victor Horsley (London) opened a debate on

The Organisation of the Profession

and advocated the establishment of a political bureau. There was, he regretted to say, a distinct feeling that medical men had nothing to do with politics, yet it was evident that legislators had a great deal to do with medical men Indeed, every member of the profession was a servant of the State Therefore, it was necessary that the profession should watch and seek to influence legislation where their interests were concerned. The British Medical Association had, it was true, appointed a Parliamentary Bills Committee, the members being selected by the branches It became a watching committee which criticised but did nothing effective The late Mr Ernest Hart did a good deal of work personally by interviewing Members of Parliament. The old constitution of the Association appeared to provide for political action but in reality it only relied on the generosity of the editor of its journal who had to devote his time gratuitously so as to save the situation The new constitution made better provision There was to be a Medico political Committee which was to study prospective legislation and to report thereon to the meeting of representatives, and the latter would determine what should be the policy of the Association Ideas and suggestions would come in from the divisions and be approved or rejected by the profession as a whole But it was further necessary to secure that these views when once ascertained should be heard in Parliament and impressed upon the Government When this was done systematically the Government would no longer treat the profession with contempt At present the profession was not properly represented in the House of Commons by the medical members

Dr Dawson Williams (London) having been called upon to speak said that the question raised was really very urgent Formerly medico political work had been done in a very casual manner and this by persons who had many other duties to perform This was notably the case in regard to his predecessor, Mr Ernest Hart. Now, Sir Victor Horsley was doing this work, studying the likely effect of Bills, &c This should be done by others and then submitted to him There were three stages in legislation which should be watched by some person especially appointed for that purpose who would be able to keep all the threads in hand and be familiar with every stage of the legislation They had to decide first what they did want and, secondly, what they did not want It was necessary to note and to ascertain the feeling within the ranks of the profession and then to watch and sometimes to counteract the agitations outside the profession Thirdly the need of action did not cease when a law had been enacted It was no easy matter to understand the effect of a new law. Under every law the methods of its application had to be carefully watched and amendments were often necessary There must be an authorised embodiment of the opinions of the profession to suggest such amendments to orders under the law

Dr Redmond protested that medical practitioners could not take political action, for they had good patients in both camps What was wanted was something like the Incorporated Law Society which would fix a minimum fee and thus enable the young practitioner to earn a living wage

Dr Major Greenwood (London) protested that the object in hand would not be promoted by abusing the medical men who were in Parliament.

Sir Victor Horsley explained that he had not said "all" the medical Members of Parliament

Mr R. H Wolstenholme (Salford) expressed some anxiety lest the political official should become the leader instead of the representative of the profession. He thought that medical men should take a full part in public life and do their duty to the community Political practitioners were the best of canvassers and if there were more of them they would have greater influence over the legislature

Mr E H. T Nash (Accrington) explained how medical practitioners could influence their local Member of Parliament and how in some instances they had done so Mr Whittaker had now abandoned a large practice so as to become an organiser for the Association He would do what was necessary The Association was wealthy and could pay sufficient to have this well done.

Mr John Wallace pointed out that Mr Whitaker would *not engineer anything but would carry out instructions* and put forward the views of the whole profession They would have to forget their party views where the interests of the profession were concerned

The President (Dr S Woodcock of Manchester) here rose to explain that the appointment of Mr Whitaker was but temporary and only an experiment, which, however, he hoped would prove successful and permanent. The late Sir Frank Lockwood had said to him "You doctors are a surprising lot of fellows Why do you not unite and agree as to what you want? With more than 20,000 men spread over the whole country and exercising great power you could get all you want. Look at the trades unions, they dictate terms"

Mr J S Whitaker (Great Yarmouth) pointed out that each division would deal with local matters and report as to how they were affected by Imperial legislation The public were bewildered, they wanted to know but could not ascertain what were the opinions of the profession There must be a double movement—from the circumference to the centre and from the centre to the circumference What came from a division must be reported by the council to all the divisions and thus the opinion of the whole Association should be known The duty of the organiser was not to initiate but to reflect the prevailing opinion Then there was the question of the relations of medical men to the political parties. Were they to follow the Irish plan of supporting either party? This was also the principle on which the liquor trade had acted He hoped that medical men would not say that their profession was their politics. They could preserve their own opinions on general political questions, but questions effecting the profession affected the general public. They opposed the Midwives Bill in the interests of the community The advocates of temperance sometimes put temperance before party and sometimes party before temperance There was much that could be done by persuasion and by the accumulation and classification of facts

Mrs. E Garrett Anderson (London) thought that the future did not depend on organisation, though it was a good thing The East Anglian branch of the British Medical Association had discussed the Midwives Bill, appointed deputations, and had usefully brought their influence to bear If all the other branches of the Association had done the same the result would have been very different.

Sir Victor Horsley, in reply, thanked Dr Dawson Williams for his lucid explanation of the difficulties to be faced in carrying on effective medico political work He hoped that Dr Redmond would bring a schedule of fees to the representative meeting at Swansea next year so that they might do what the lawyers had done. Dr Greenwood laboured under a misapprehension The speaker had not meant that medical men should conspire with a medical party, but he did aise as a question of principle the manner in which hey should deal with Members of Parliament and urged hat it was necessary to mention their names if it was esired to influence them. It was very well to talk of onciliation in reality it meant full surrender Members f Parliament had their own axes to grind. They would not isten to representations that were not backed by force. It vas not possible to conciliate, it was only possible to frighten Ir Nash and others had shown what could be done locally nd it would be the duty of the divisions to educate their Jembers of Parliament. Then there was the question as to ow far the new constitution converted the British Medical sociation into a trade union. There was, however one ital difference. The trade unions only took in hand the vages question. The medical profession had always aken into consideration ethical conduct. If a member lisgraced himself he was arraigned The medical profession lso worked more for the general public than the trade nions But in regard to united action and mutual help nd support he hoped that the members of the profession vould imitate the trade unions.

Dr E. JEPSON (Durham) read a short paper on

How to Form a Medical Union.

Ie gave a history of the County of Durham Medical Union[1] nd insisted that the leaders should make visiting tours nd that there should be well-defined punitive measures n the north they were studying how to establish a minimum ee and how to do away with contract work altogether

Dr J H HUNTER (South Shields) read a paper on the ame subject and urged that the cost of qualification entitled he practitioner to a competent livelihood and yet many ailed to secure enough to provide for themselves and amilies. This was not due to improvidence or to the overcrowding of the profession but to sweating of medical men. After quoting THE LANCET Special Commissioner s reports to how that practitioners received but from *2d.* to *4d* er consultation he urged that organisation was imperatively needed. The resident medical officer of the ocal hospital might often be useful as a neutral organiser Local practitioners should meet privately tabulate their grievances canvass the profession and when the majority had agreed to form a union then a public meeting should be convoked and the organisation formally constituted Those who remained outside would join in time. By following trade-union tactics they were doing nothing derogatory to their dignity, on the contrary it was the only practical means of defending the dignity of the profession

Dr ALFRED COX (Gateshead) raised the very important question as to what was going to become of the medical unions, for they had acquired some vested interests which they might not feel inclined to abandon so as to become divisions of the newly constituted British Medical Association. These unions would have to appeal to such of their members who were not also members of the British Medical Association to join the latter body and to pay 25*s.* a year The speaker thought that all local and special organisations should be sunk in favour of the one great Association. Yet some of these smaller bodies would die hard They had nevertheless nothing to lose. There was no reason why the South Shields Medical Union which had already abandoned its local independence so as to become a branch of the County of Durham Medical Union should not now become a division of the British Medical Association

Dr T LAFFAN (Cashel) complained that there were still back-door entrances to the profession which should be closed so as to prevent overcrowding

Surgeon Major G K. POOLE (late I M.S.) thought that the profession was in a lamentable position and that medical men were all pulling against each other There were only about 150 medical men who attended the two recent meetings of the profession held in London.

Dr R. E. HOWELL (Middlesbrough) thought that if the profession was not yet well organised the spirit of union was among them. But for the medical union in his town he could not run the risk of absenting himself now however competition was replaced by coöperation.

Mr WOLSTENHOLME (Salford) was also concerned as to what would befall the local organisation in face of the new constitution. They had been asked to commit suicide. But there was enough work for them to do outside the ranks of the British Medical Association. Nor need they fear the expense. In Manchester their medical guild had a quarterly journal and for the sake of the profits that that paper brought in the publishers had offered to pay all the working expenses of their guild

Mr G H. BROADBENT (Manchester) replied that this offer should make them suspicious and showed that the guild had better do its own work. He did not agree with Dr Cox and was strongly of opinion that the local medical unions or guilds should be kept in existence. The other and vast scheme would take a long time to grow and then it was not at all certain that it would do the work for which the medical unions had been founded. There had never been much cohesion in the British Medical Association. The guilds and the unions alone had achieved tangible results. They had promoted unity and cohesion and must continue their good work and not abandon a reality for what as yet was but a scheme.

Mr NASH remarked that some of the unions had money in their banks, where it had accumulated to provide means for taking legal action against quacks and for other purposes They had got rid of several quacks with the aid of these funds and he did not believe that the British Medical Association was going to do this work for them therefore he was opposed to the policy of suicide.

Dr S CRAWSHAW (Ashton under Lyne) thought that the existing organisations could continue as at present and that it would only be necessary to change their name. The only point was that their rules would have to be submitted to the Council of the British Medical Association but he saw no reason why these rules should not be approved by the Council.

Dr JEPSON thought that each union would have to decide for itself whether it would join the British Medical Association and he believed that in the course of time the unions would for the most part do so

Dr HUDSON did not think that they were killing local organisations but only altering their names

The PRESIDENT now rose to announce that it was time to close the debate saying that the questions raised could not be settled till more experience had been acquired.

The Vaccination Question

Barely an hour remained before the time of final adjournment and during that short period an attempt was made to discuss the question of the application of the vaccination laws.

Mr R. F TOMLIN (London) read a paper dealing to some extent with the quality of the lymph and the nature of the marks

Mr DAVID OWEN (Manchester) urged that parents should be able to select any practitioner to vaccinate their children and that the cost should be defrayed by the State as in the case of public vaccinators

This led to a somewhat animated debate between public vaccinators and private practitioners but the remaining hour elapsed before any decision could be arrived at beyond the adoption of a resolution to the effect—

> That in the opinion of this section no alteration in the Vaccination Acts will be satisfactory which does not provide a standard of efficiency for all practitioners alike

Other proposals were brought forward but the PRESIDENT declared that there was not time to take them into consideration and accordingly left the chair This gave rise to some protests and the section broke up in confusion.

NAVY ARMY AND AMBULANCE.

THURSDAY JULY 31ST

Inspector-General A. TURNBULL, R N retired (London) opened the proceedings of this section by a paper entitled

The Prevention of Scurvy

He said that the absence of scurvy from Nansen's expedition had not received the recognition to which it was entitled. The British Arctic Expedition of 1875 failed as the result of scurvy on board the *Discovery* and *Alert* though every precaution thought necessary at that time was taken to prevent scurvy. Osler had stated that the etiology of scurvy was still undecided. Osler gave three suggested causes for the disease (1) the absence of vegetables or ingredient supplied by vegetables (2) the presence of some toxic material present in the food and (3) the presence of some organism in the food The speaker thought that the evidence was overwhelming that the disease arose from a lack of some essential element and not from food allowed to become tainted He went on to say that, judging from extensive researches, the exciting cause was some toxic material in the food and that lime juice, though an unquestioned remedy, was not a preventive and was erroneously so supposed The present absence of scurvy from the navy was due to the changed and varied dietary The late Dr Curnow and Dr Johnston attributed the lessening of scurvy at the *Dreadnought* Hospital to (1) the Merchant Shipping Act, 1867, (2) the increase of steamships, and (3) the decline of sailing vessels. Scurvy they found was limited to the ordinary seamen of sailing ships, particularly of the East Indian trade, and was essentially a disease of the forecastle Patients were admitted who had regularly taken lime-juice This showed that lime juice was an adjuvant to the prevention of, and not an absolute deterrent to, scurvy Nansen, under the advice of Professor Torup of Christiania, had established a proper anti scorbutic diet. And yet Nansen and Johannsen, after great hardships and privations, living on their rifles, arrived home in robust health This was due to the fresh meat food which they procured The crew of the *Fram* had little fresh meat and no lime juice yet did not get scurvy The speaker quoted the Jackson Harmsworth expedition which trusted to sound provisions and escaped scurvy, and the *Windward* which trusted to lime-juice had to contend with scurvy He then touched on the cost of lime juice to the Royal Navy in 1900 (£1500) and mentioned the theory of sterilised milk foods causing scurvy rickets as being refuted by Ransom, Holt, and Cautley Antiseptic surgery was purity, true anti scorbutic measures meant pure food

---

[1] We have already published this history see THE LANCET March 9th (p. 740) and 16th (p. 819) 1901

The PRESIDENT (Brigade Surgeon Lieutenant-Colonel G S ELLISTON) thanked Inspector General Turnbull for his interesting paper and its very valuable details and hoped that in the Royal Navy scurvy was an extinct disease. Improved feeding and ventilation had no doubt much to do with the improvement.

Fleet-Surgeon G KIRKER said that he had not had much experience of scurvy except when a student He did not agree that it was due to decomposed food and thought it was due to the absence of fresh animal and vegetable food The Nansen expedition depended on their rifles for the most part and had no scurvy, principally because of the fresh food thus provided. In treating scurvy Coppinger depended more on fresh meat than on lime juice

Surgeon Major G A. HUTTON said that the captains of ships might be allowed to alter the diets as a remedy against scurvy It was, of course, a serious question, as it would be difficult to bring about a change from a regular diet. It was doubtful even whether such a responsibility should be placed on the commander The short voyages of the present day and the easy obtaining of fresh provisions were great preventives In his first voyage from Plymouth to Cape Town the vessel took 65 days, in these times it took only a fortnight.

Inspector General TURNBULL, in reply, said that Fleet-Surgeon Kirker agreed with his plea for fresh and pure food The American navy did not issue lime juice. In the Nares expedition the people were better provisioned and the officers took port wine The pemmican was very unappetising He was not wedded to the ptomaine theory but advocated pure fresh food. In the case of dietary he had given evidence before the Admiralty Committee and had suggested a dietary for war service which would be useful in times of scarcity

Surgeon Major HUTTON read a paper entitled

Voluntary Aid to the Sick and Wounded in War, with Special Reference to Hospital Orderlies

He quoted Sir John Furley, the Chief Commissioner of the Red Cross Society in South Africa, who said, "In no army can the medical department be made equal to the exigencies of a great war without supplementary aid from voluntary societies, and no such societies can properly fulfil that duty without preparation and organisation in time of peace" The main object of his paper, as the title indicated, was the future supply of hospital orderlies The St. John Ambulance Association had, during the South African war, furnished through its ambulance brigade upwards of 2000 men who had acted as orderlies in the various military hospitals at the seat of war and in the hospital ships, and excellent accounts had been received on all sides as to the way these men had done their arduous duties 65 of these men had succumbed to disease contracted in the performance of their noble work, eight had been mentioned in despatches, and one had received the distinguished service medal. The question of the supply of efficient hospital orderlies was a pressing one Sir Frederick Treves had said at the meeting of the British Medical Association at Ipswich that "the question of orderlies is a difficult one The present campaign showed that nurses —keenly as their services were appreciated—could not work in the field hospitals and they must fall back on the orderly, and he was almost an impossible person It was indeed in fact, very difficult to know what his position was He had to pitch tents, to dig trenches, and then to nurse complicated cases" It was almost an impossible position. Those who criticised the hospital orderly had no knowledge of the extreme difficulty of this subject Where were they to be got? Besides the St John Ambulance Association and Brigade another source of supply of hospital orderlies might be from the Volunteer Brigade Bearer Companies

Colonel A W DUKE, R A.M.C, said that the St. John Ambulance people in Africa were good fellows and most willing to learn and to work. It was most necessary for teaching officers to remember that these men should be brought into the hospitals There should be two classes of army hospital orderly From 5*s* to 6*s* a day should be given to the men who did the real nursing work and the other men could do the cleaning The subject of the two classes of orderlies ought to be pressed upon the War Office.

Surgeon General J B HAMILTON, retired, said that when he joined, any old soldier was used as hospital orderly The Army Hospital Corps was gradually developed At the beginning the men were under the military officers for discipline only Eventually, after much trouble, they obtained command of their own men At first they got good men but the military authorities took them and eventually they had to put up with men below the standard required. The two classes of orderly was a most important matter and should at once be seriously undertaken. The men should be tentatively employed until it was seen how they would turn out. It was as necessary for an orderly to have military instruction as it was for a soldier in the interests of discipline He had succeeded in getting nurses registered for service in the War Office Preparation in advance was the thing—not scramble after war had broken out

Surgeon Major G H DARWIN said that the St John Ambulance men would be good men if they would only keep up their practical work, if they would do this they would be the best possible men For the future the men would have to come from the Medical Staff Corps

Dr FORBES ROSS (London) said that, speaking as a civilian, it was nothing less than a miracle surpassing every other recorded that in spite of the material as regards orderlies which the Royal Army Medical Corps had to deal with they had done so magnificently in South Africa. Their organisation must have been superb and if their efficiency had not been good they could never have coped with their difficulties as they had done There was an apparent need for a "nursing ward orderly" in all military hospitals There ought to be a "dresser sergeant," a "dresser corporal," and two "dresser privates" kept entirely and solely for dressing surgical cases and nursing medical cases Surely a man of the clerk class could be taught antiseptic surgical dressing, just as were ordinary medical students, and set to help the surgeons when on active service and in hospital, 30*s* a week and rations and allowances would procure the right class of man. His uniform should be different from the other orderlies of the Royal Army Medical Corps and he should not be permitted to do dirty jobs about camps Government colonial hospitals were equipped with trained dressers and there was no reason why this could not be done at home

Surgeon Major POOLE thought that the idea of the two classes of orderly was an excellent one The higher grade orderly should be drawn from the lower grade men. The need for male nurses was a great one and male nurses ought to be used largely

Deputy Commissioner C H. MILBURN (St. John Ambulance Brigade) said that the St. John Ambulance Brigade and the St. John Ambulance Association should be clearly distinguished The brigade had done a great deal of the organisation for the war The men ought to have hospital training The first and second grade of orderly would come and was a most important and necessary matter The civil organisation which had helped the army should have been thanked by the Government. The St. John Ambulance people had not been thanked.

The PRESIDENT said here that the King had had the proper thanks conveyed and that was the main matter and the speaker cordially agreed.

Lieutenant-Colonel J HYSLOP D S.O (Natal) said that the matter of the civilian element was very pressing. The Royal Army Medical Corps administration was admirable. If the St John Ambulance men had been trained in the same way as the Royal Army Medical Corps orderlies they would have been immeasurably superior as they were drawn from a more intelligent class

Assistant Commissioner J S GRIFFITHS said that he had tried to organise the St. John Ambulance Brigade in Bristol into a more military body and drilled them and found them most efficient.

Captain W B PRITCHARD R.A.M Ó. (Volunteers) thought that the Royal Army Medical Corps was a better training ground for orderlies than the St. John Ambulance for disciplinary reasons. As regards the ambulance work the St. John Ambulance Association was most efficient. The men ought to be trained in hospitals in the nursing part of their work. He thought that the Royal Army Medical Corps Volunteers had not been accorded proper recognition.

The PRESIDENT thought that the volunteer medical corps had gained a great distinction by its incorporation with the Royal Army Medical Corps. The St. John Ambulance Brigade had had some hospital training They had most undoubtedly a great deal of discipline for the ambulance men were required to attend annual drills and parades and if they did not they were turned out. Men in the bearer companies should be under their own officers who had trained them as far as possible and it was a grievance if that were not so

Surgeon Major HUTTON in reply said that army orderlies did their duties fairly well in the old days. It was gratifying that the St John Ambulance men were found so good in South Africa. The object was to get good men to enlist in the Royal Army Medical Corps as orderlies He *was in the St. John ambulance work before the formation of* the Brigade The Association and the Brigade were inseparably connected and the greatest cordiality existed. With regard to the two classes of orderlies it was extremely desirable but presented certain difficulties The large hospitals no doubt would be very glad to give any assistance in the hospital training of the St. John Ambulance Association.

Surgeon General HAMILTON here read out the new suggestion of having representative members for the three services on the council—navy army and Indian medical *services—and suggested that they should be retired members* as they could be the only people who could open their mouths freely Their election could be effected by means of the *British Medical Journal.*

The meeting unanimously endorsed a resolution suggesting to the council of the Association that a small committee, consisting of Inspector General Turnbull Surgeon General Hamilton, and Brigade-Surgeon Lieutenant-Colonel Drake-Brockman, be formed to look into the necessary arrangements.

FRIDAY AUGUST 1ST

Deputy Inspector-General JAMES PORTER, R.N opened the proceedings by the contribution of a paper entitled

The Red Cross Badge

He reviewed the question of the abuse of the red-cross flag in South Africa and stated that owing to long range shooting and the difficulty of seeing the flag at long distances that it was to be expected that it would sometimes be fired on in mistake, and at most in future it must be regarded as indicating where help and medical aid could be obtained rather than as a protection to the wounded He reviewed and recounted the numerous reported instances where the Boers in the late war made improper use of the red-cross flag and mentioned the various and numerous vehicles taken during the war which were adorned with the red cross but which had undoubtedly been used for other purposes. He pointed out that in naval work the red-cross flag might be taken for the admiral's badge and thus draw fire on a hospital ship. Some authoritative ruling should be obtained with regard to whether Government hospital ships were capturable as prizes of war He finally summed up as follows (1) the Geneva badge, whilst readily recognisable should not be easily counterfeited or be confusable with any other badge or flag, (2) it should be issued under authority only along with means of proving the identity of the holder, and (3) abuses of the badge should entail definite penalties, swift and severe.

Surgeon General HAMILTON retired, thought that wagons for the use of the sick ought to be painted white, and not khaki as were those which were used for military purposes. He did not see how we could blame the enemy on a dull day for firing on a red-cross wagon painted khaki, as it was difficult to see the red cross.

Lieutenant-Colonel HYSLOP said that the individual wearing the red cross was absolutely unprotected, as at long range the cross could not be seen

Surgeon General HAMILTON read a paper entitled

Reform in the Army Medical Service

He briefly reviewed the history of the difficulties experienced in attaining their present satisfactory position. The jealousies of the combatant branch which led to petty acts of irritation unworthy of so noble a body of men were caustically dealt with. He then alluded to the war in South Africa and commended the retired medical officers and civilians, and said that the civilians should have been given temporary commissions and uniforms as they were entitled to it, many of them lost their lives as the result of their services. This omission of commissions and uniforms was a great mistake on the part of the War Office He strongly criticised the treatment of the late Director General Jameson and stated that some recognition should undoubtedly have been given him. He reviewed the situation as altered by the new Warrant and commended the position awarded to the new Director General He thought that the Royal Army Medical Corps in India should have the same rate of pay and hospital allowances as at home. The social position accorded the *personnel* of the Royal Army Medical Corps should undergo improvement or it would injure the working of the new Warrant. His Majesty's honorary medical officers in the army were never asked to Court functions as were other officers of other branches.

Surgeon Major G A. HUTTON said that he could well understand Surgeon-General Hamilton's remarks. It was regrettable that when officers rose to the higher ranks they became merely clerks and lost their professional attainments as physicians and surgeons. He thought that junior officers should be more considerately treated by their seniors and this would bring about a sound *esprit de corps* as it would encourage them to persevere.

Dr FORBES ROSS said that from a purely civilian point of view it had always puzzled him why the army medical man seemed to be so much in doubt and so touchy as to his social position. Social status was mainly a personal matter a gentleman was always a gentleman and remained so and would be treated as such whatever anyone else might decide, and no amount of official recognition would transform a cad into a gentleman. Medical men from their general and professional education were much better informed on many subjects than many soldiers, therefore it did not behove them as a profession to descend to petty jealousies It behoved the members of the Royal Army Medical Corps to be loyal and considerate to one another—senior to junior and *vice versa*—as professional brothers and then the other branches of the service would regard them differently

Dr. G H. DARWIN (Manchester) related an amusing episode in his volunteer mess to the effect that having been treated very uncivilly by some volunteer brother officers and an argument in consequence having arisen he had stated that he himself the doctor" the chaplain, and the veterinary surgeon were the only people present whose callings were real the other gentlemen being only shams" which greatly discomfited his opponents and eventually led to more courteous treatment of himself by the sham combatants.

The PRESIDENT said that Surgeon General Jameson was badly treated as his advice at the beginning of the war was against the abolition of the sanitary officer and the result showed that he was right. The Queen Alexandra Nursing Corps was a good move, as enteric fever and pneumonia could not be nursed by ordinary orderlies.

Captain PRITCHARD thought that the age of joining the service should be raised and very young men should not be admitted as they had no experience He thought that social position as a medical man was what was most desirable and he did not care very much for their opinion of himself as a soldier so long as he received that due to a professional man and a gentleman.

Surgeon General HAMILTON, in reply said that no doubt the social matter would right itself, but up till now many discourtesies had to be put up with which were very galling. He did not agree that the age of entry into the service should be raised, as the officer did not learn discipline and became imbued with the military spirit unless he began young. A man entering at 28 years of age had very little chance of promotion and as a result excellent men had to retire on account of age. The age should be not under 22 years and not over 26 years. The medical officer in the army was more than a medical man when on the battlefield.

Mr C. ROBERTS, late civil surgeon in Government employ in South Africa, read a paper entitled

The Treatment of Abdominal Wounds in War

He said that in discussing the treatment of abdominal wounds in war it was necessary to consider (1) the nature of the injury, (2) the cases in which operative interference was indicated, and (3) to what extent the prospect of success of abdominal operations was diminished by the difficulties inseparable from campaigning. When the wound was caused by a high velocity and mantled bullet of small calibre—as the Mauser and Lee Metford—the extent of the visceral injury depended little, if at all, upon the range at which the bullet was fired, except in some instances in which the wound was complicated by injury to bone. At very long ranges, when the force was spent and in ricochet wounds, the bullet might be retained. The course it took within the abdomen was then lost and the internal injuries might be widespread and with difficulty made out. Where both wounds of entry and exit were present the track was always that of a straight line between these two points, and from anatomical knowledge one was able to say what viscera might have been injured. Transverse wounds were more fatal than those passing in an antero-posterior direction. Wounds above the umbilicus were more favourable than those below. Direct antero-posterior wounds in the small intestinal area were very unfavourable. Complete transverse wounds above the umbilicus were very unfavourable. That the small intestinal area might be crossed without perforation occurring had been demonstrated. 1. By examination after death. In the published record of the work of the Portland Hospital in South Africa written by the professional staff a case was described the details of which were supplied by Mr G. L. Cheatle. Two perforations were found in the cæcum and sigmoid flexure of the colon and though the bullet had undoubtedly crossed the area occupied by the small intestine no wound of the bowel had occurred. 2. By examination during laparotomy. Mr Makins in his work on his surgical experiences in South Africa had given an account of an operation in which two linear rents were found in the jejunum, involving the peritoneal and muscular coats only. He had also noted in other instances linear ecchymoses and wounds of the peritoneal and muscular coats alone associated with complete perforations. The view that the intestine escaped perforation in many of the cases that recovered was supported by the fact that frequently so few abdominal symptoms were present. It was difficult to believe, however, that in all cases no perforation was present, for in many shock was severe and frequent vomiting persisted for two or three days, the temperature rose, and the abdomen became rigid and painful. These symptoms were readily attributable to the shock of perforation and slight local peritoneal infection. The post-mortem examination in Mr Cheatle's case previously mentioned showed that no extravasation of fæces had occurred from a perforation of the cæcum and in cases operated upon no free escape of fæces had been found before manipulation. Sometimes the presence of melæna had furnished strong evidence of perforation. There was little doubt that a perforation might heal primarily or become shut off by adhesion to a neighbouring coil within a few hours. In considering the cases in which operative interference was required one must first exclude those wounded which would die in the first 24 hours from intra peritoneal hæmorrhage or from the shock of extensive internal injuries and which were not amenable to surgical treatment. Their number was always considerable, probably from 20 per cent. to 30 per cent of those wounded. Where increasing intra peritoneal hæmorrhage was threatening life and the surroundings and general condition of the patient allowed of it laparotomy should always be performed and the bleeding arrested, whether from torn vessels in the omentum or mesentery or from laceration of the liver or spleen. Only too often, however, extensive visceral injuries would also be found and a favourable result would not be obtained. Wounds of the liver, kidney, and spleen, as a rule, healed well, and when hæmorrhage was not dangerous required no operative treatment except for secondary complications, such as biliary fistula, hydronephrosis, or perinephric abscess. Laparotomy might be required when perforation of the stomach or bowel might have taken place. If one excluded those who died in the first 24 hours one might estimate that of the cases of penetrating abdominal wounds amenable to surgical treatment about 60 per cent. would recover. The recoveries, however, were chiefly amongst those cases in which the area of the small intestine was not crossed and when this area was involved the mortality was probably very great. Too often without exploration one could not be sure whether perforation existed or not, and whilst a routine laparotomy was not justifiable in every case it should be performed at the first evidence that perforation existed. Such evidence might be found in the persistence of shock, a steady increase in the rate of pulse, and in the abdomen becoming increasingly rigid and tender, and especially was it probable if vomiting had persisted and the passage of flatus was arrested. In these circumstances, and when the surroundings were such as not to expose the patient to fresh dangers, the operation should not be delayed, and the apertures might be dealt with by suturing or the area of the wound might be resected, according to the condition found. Especially was the operation likely to prove successful when the injury was localised, the patient was seen within six hours of being wounded, and transport had not been difficult. When the bullet was retained or the track was a complete transverse one the prognosis was far less favourable. The results of laparotomy for gunshot wounds in war had been most unfavourable. In the Spanish American war Senn reported that all cases he knew of that had been operated on died. In the Tirah campaign, of eight cases of penetrating wounds of the abdomen five had been operated on and all died. In the Boer war he (the speaker) only knew of two successful operations performed for wounds of the small intestine. In the American war in the Philippines Dr Robinson reported that five cases had been operated on and four died. The unfavourable results were attributable to various causes. The severity of the injuries, the delay in bringing in the wounded, difficult transport, and the unfavourable surroundings rendered abdominal operations at the front in most cases unpermissible. One was led to the following conclusions. 1. That as a rule the conditions in a field hospital were not suitable for performing laparotomy. Moreover, many patients with penetrating abdominal wounds recovered without operation, and in the majority of those who died the nature of the injury was such that death must have resulted whatever had been the conditions of operation and an exploratory laparotomy might add a fresh danger to the patient. 2. When occasions arose in which the conditions of operation approximated to those in civil practice laparotomy should be undertaken, for increasing intra-peritoneal hæmorrhage must endanger life. Also when there was evidence that perforation of the stomach or bowel existed, provided that the patient was seen early enough, laparotomy was called for.

The PRESIDENT commended the paper for its valuable practical suggestions and invited discussion.

Dr FORBES ROSS said that Mr Roberts's excellent paper tended to support the predictions made by Mr Clinton Dent and Sir Frederick Treves, "that the small-bore bullet was a most humane missile." In cases of abdominal injury from small bore bullets experience would tend to show that the surgeon would be more deadly than "our friend the enemy." It would now become an accepted axiom not to operate in injuries of the abdomen inflicted by a small bore bullet unless forced to do so by urgent symptoms.

Brigade Surgeon Lieutenant-Colonel P. B. GILES contributed a paper (*in absentiâ*) entitled

The Brigade Medical Unit

He stated that under modern conditions of extended front and long range fire extra individual teaching for the regimental stretcher bearer would be necessary. The men should be taught the principles of first-aid and also how to take advantage of cover whilst approaching the wounded. The regimental medical officer should have a non commissioned officer of the Royal Army Medical Corps instead of from the regiment. The bearer companies and the field hospital should be joined as one unit under one command and not be distinct as hitherto Field hospitals should be placed as near the field of action as possible, but not so as to interfere with any position of strategy and should never be pitched at a distance from a good road if available

The PRESIDENT then put a motion to the meeting proposed by Surgeon General HAMILTON and seconded by Lieutenant Colonel HYSLOP D S O to the effect—

> That ambulance wagons should be painted a conspicuous colour preferably white for coolness, and should be provided with a red-cross flag much larger than was hitherto used.

The motion was carried unanimously

The business of the section was concluded by a cordial vote of thanks to the President for discharging in so genial and able a manner his arduous duties, and Dr FORBES ROSS in proposing this vote of thanks which was seconded by Inspector General TURNBULL, R.N said that the 1902 meeting at Manchester would be memorable in that at that meeting the members were allowed to indulge in the 'weed.

The PRESIDENT briefly replied.

TROPICAL DISEASES.

FRIDAY AUGUST 1ST

Mr JAMES CANTLIE (London) opened the discussion on

Yellow Fever

by stating the conclusions arrived at by the United States Army Commission in Cuba. The Commission had demonstrated (1) the fact that none of the bacilli hitherto described including that of Sanarelli, played any part in the etiology of yellow fever (2) that no bacillus or other organism could be found in fresh blood in defibrinated blood or in blood diluted and filtered through a Berkefeld filter and therefore that either our methods of investigation are faulty or that the germ is ultra microscopic, or that no germ exists , (3) that the specific agent of yellow fever was destroyed by exposure for 10 minutes to a temperature of 55° C (4) that the blood taken from a yellow fever patient and injected into healthy non immune persons caused the disease and that defibrinated blood and blood passed through a Berkefeld filter also caused the disease (5) that fomites did not convey the disease (this was tested in the most thorough fashion and proved beyond doubt) , (6) that the mosquito—the stegomyia fasciata—after having fed on a patient suffering from yellow fever caused by its bite the disease in healthy non immune persons (7) that the mosquito could not convey the disease until 12 days after feeding and (8) that the mosquito was capable of conveying the disease 57 days after it had fed on yellow fever patients. Mr Cantlie mentioned various diseases in which yellowness of the skin occurred independently of biliary obstruction. Amongst these he mentioned acute yellow atrophy bilious remittent, relapsing fever and bilious typhoid fever The last-named was especially prevalent in Egypt for in the early days of the last century it was named yellow fever and was still frequently so termed. He thought it possible that yellow fever was more widespread than the literature at the present day allowed

Dr GEORGE C LOW Craggs Scholar London School of Tropical Medicine, sent a paper on

The Differential Diagnosis of Yellow Fever and Malignant Malaria.

Dr Low stated that the diagnosis of yellow fever on its first occurring in a non-endemic area where malaria was prevalent was often by no means a simple affair The facial appearance the condition of the tongue, the state of the skin, the relation of the temperature and the pulse the presence of albumin in the urine, epigastric pain the vomit, hæmaturia, and the condition of the nervous system all of which were described in text-books as features by which yellow fever might be diagnosed, were quite untrustworthy The only positive diagnosis was by a blood examination and even then it must be remembered that malaria parasites might co-exist in the blood with the poison of yellow fever Post mortem the characteristic malarial pigment the localisation of parasites in the brain, spleen or gastric mucosa at once declared the cause to be malarial and in yellow fever the liver showed the typical fatty degeneration.

Dr PATRICK MANSON C.M.G F.R.S (London), drew attention to the possible errors in the experiments of the United States Army Commission and pointed out that in the experiments made by passing blood through a Berkefeld filter the blood from only one patient had been used.

Dr L. W SAMBON thought that the diagnosis between malaria and yellow fever would be much easier when they had succeeded in separating blackwater fever from the intermittent fever with which it was now confounded. It was difficult at times to diagnose blackwater fever from yellow fever Hæmoglobinuria was, as a rule, absent in yellow fever yet he held that the existence of blackwater fever on the west coast of Africa was greatly responsible for the notion that yellow fever prevailed there.

Malta Fever

Mr P W BASSETT SMITH staff surgeon R N (Haslar), contributed a paper on

The Agglutinating Properties in the Blood in Cases of Mediterranean Fever with Special Regard to Prognosis with Remarks on other Blood Changes and Reactions during the Course of the Disease

In the wards of Haslar Hospital as many as 198 cases of Mediterranean or Malta fever had been treated during the past two and a half years The agglutination of the micrococcus melitensis when brought in contact with dilutions of blood of patients suffering from malta fever was early established and became an efficient method for diagnosis The agglutinating properties commenced early (five days) and lasted long (one and a half years). The technique employed consisted in using an emulsion made from a five days old agar culture of the micrococcus in saline solution this was drawn up into sterile pipettes and killed at 65° C. for a period of 15 minutes, the same series of pipettes being utilised throughout in the cases The blood was centrifugalised and the serum generally employed a few hours after it was obtained the dilutions were made with a measuring pipette as recommended by Professor Wright, an equal part of diluted serum (20 cubic millimetres) and emulsion being always used so that the number of organisms present in each sedimentation tube was approximately the same in each instance. These were left at room temperature for 24 hours and the results then recorded the dilutions ranging from 1 in 20 to 1 in 2000 Equal parts of clear blood serum were drawn up in tubes with spiral twist incubated at 37° C. for 24 hours and then blown out on thick agar plates which were incubated for from three to seven days, when the presence or absence of growth of the micrococcus melitensis could be observed. If there was no growth one inferred that the serum had been able to kill off the organisms present in that dilution and so estimate the bactericidal power which was in all cases very considerably less than that found against the typhoid organism Mr Bassett-Smith also drew attention to the phagocytic power of leucocytes and to the general blood changes in the disease.

Mr JAMES A. HISLOP (Assam) contributed a paper on

The Geographical Distribution of Malta Fever and the Value of Splenic Enlargements as a Test of Malarial Incidence

Mr Hislop drew attention to some cases of Malta fever which he had observed in Assam and believed that many fevers classed as malaria and remittent fever would be found to be Malta fever The serum test had given positive results in several cases and the charts showed the undulant nature of the temperature. Mr Hislop described a form of fever in Assam which was absolutely resistant to large doses of quinine and yet accompanied by great enlargement of the spleen. He believed this to be a specific form of disease independent of malarial infection and requiring further investigation and interpretation.

Dr C. A. BENTLEY (Tezpur Assam) contributed a paper entitled

Kala-azar as an Analogous Disease to Malta Fever Preliminary Notes of an Investigation and some Discoveries regarding the Nature and Condition known as Kala-azar

This disease had been attributed to ankylostomiasis to an intense form of malarial fever and to post malarial cachexia Dr Bentley concluded that kala azar had nothing to do with malaria in any form but was a distinct disease By none of the three tests for malaria—viz. periodicity the effect of quinine or the microscopic examination of the blood—could kala-azar be in any way associated with malarial fever In summing up the result of his investigations Dr Bentley said The hæmatology of kala-azar lends no support to the malarial theory of origin, while it corresponds to the little at present known of the blood conditions of Malta fever "

Dr BRIAN MELLAND (Bowdon) read a paper on

Malta Fever in the Canaries

Dr MANSON, in criticising the statements made as to the presence of Malta fever in India and the identity of kala azar with this disease, said that too much reliance seemed to have been placed on the agglutination tests He related an instance in which he submitted a case of doubtful fever to three experts one affirmed that the blood gave the reaction of Malta fever, a second declared that it was from a person suffering from typhoid fever, and a third that it was neither Malta fever nor typhoid fever He would ask investigators not to place too great reliance upon serum tests in cases of doubtful forms of illness

Professor GALLI-VALERIO (University of Lausanne) contributed a paper entitled

Contribution to the Study of Bacillus Pestis, its Cultural and Morphological Characters and its Relations with Bacillus Pseudo tuberculosis Rodentium

He dealt first with the characters of the cultures of bacillus pestis , secondly with the morphology of bacillus pestis, and thirdly, compared the bacillus pestis with bacillus pseudotuberculosis rodentium He maintained that confusion in the diagnosis of plague by the inoculation of guinea-pigs might arise from the fact that the bacillus pseudo-tuberculosis might be present in the guinea pig and the two bacilli exhibited many points in common.

Dr SAMBON read a paper on

Remarks concerning the Nomenclature, Etiology, and Prophylaxis of the Intermittent Fevers

He recommended that the term "malaria" ought to be abolished. The old name "intermittent fevers" might be continued or the term "hæmocytozoal fevers" adopted The name "æstivo autumnal" was inappropriate , "tropical malaria" gave a false notion of the widespread nature of the disease, which went beyond the tropics. The old terms "semi tertian" or "sub-tertian" were worthy of re instatement The name "plasmodium" applied to the parasite was most inappropriate Dr Sambon was of the opinion that the parasites of quartan, tertian, and subtertian (æstivo-autumnal) should be classed in one genus and called respectively hæmamœba Golgii, hæmamœba vivax, and hæmamœba Laverani.

Dr MANSON stated that he agreed with Dr Sambon's nomenclature

Surgeon-Major G K. POOLE (London) remarked that he had seen quartan fever in Eastern Bengal.

ASYLUM REPORTS

Dorset County Asylum (Annual Report for 1901) —The average number of patients resident during the year was 732, comprising 359 males and 373 females. The admissions during the year amounted to 145—viz , 73 males and 72 females Of these 119 were first admissions Dr P W Macdonald, the medical superintendent states in his report that the past two or three years of national excitement and tension have had an influence on the male admission rate, which now shows a tendency to increase "Recent experience lends credence to the opinion that strain and exposure are having their victims even among the strong and healthy, and it has to be admitted that a percentage of these cases are finding their way into institutions for the treatment of mental disease " Whether such cases are to be regarded as due to exceptional stresses and trying circumstances connected with the war or are merely the ordinary result of active service it is difficult to say , but such cases were found to be the most hopeless and least favourable as regards prospect of recovery among the admissions, and "their one outstanding characteristic was the complete and painful early dementia." The admission rate was somewhat higher than usual, but this was not compensated for by any general improvement in the character of the cases. "The female patients as a class were less favourable than the males and several were the subjects of grave physical ailments " As regards the males, 70 per cent. were classed as incurable on admission, and in the case of the women the proportion of incurable patients was as high as 80 per cent. The unfavourable and hopeless character of the admissions was not associated with any particular form of mental disease. A large increase appeared in the proportion of aged patients among the admissions The senile cases were "unfavourable as regards any hope of recovery and it is to be regretted," adds Dr Macdonald, "that these aged men and women could not be cared for elsewhere." Worry and anxiety accounted for 12 per cent. and hereditary predisposition to insanity was traceable in 45 per cent. of the admissions The number of patients discharged as recovered during the year amounted to 50—viz., 22 males and 28 females, or 6 8 per cent. of the average number resident. The deaths during the year amounted to 47—viz , 24 males and 23 females, or 6 4 per cent as calculated on the same basis Of the deaths two were due to renal disease, two each to bronchitis and to phthisis, four to cerebral hæmorrhage, five each to senile decay and cerebral degeneration, six to cardiac disease, and the rest to other causes The committee of management states in its report that plans for a separate new building for the use of private patients have been prepared and approved of and that the work will be shortly proceeded with The weekly maintenance rate for patients has remained at 9*s* 4*d* during the year The report of the Commissioners in Lunacy is not appended

TUBE RAILWAYS

THE concentration within the heart of London of the radiating lines of traffic from the growing suburbs, and the chronic upheaval of the streets consequent upon the tangle of sewers, hydraulic power, water, and gas mains, besides telegraph, telephone, and electric lighting cables, have produced such a state of congestion as to be insupportable. The necessity for rapid communication between the extremes of the outer circle with the centre of the metropolis and with each other, in view of the vast population of London, is a sufficient reason for welcoming any proposal that promises relief. In the following article we propose to touch briefly upon those points in the now numerous schemes for tube railways in London which have a bearing upon the public health of the metropolis in a comprehensive sense

There is a natural tendency for promoters of proposed tube lines, with an eye to dividends, to tap the more populous districts, but their lines should not be permitted to terminate here or facilities for locomotion will but increase the already overcrowded condition of these parts The new lines should pass on to more open country and those that contemplate the establishment of direct communication between extreme points of London, from north to south or east to west, providing for the proper expansion of the city, are certainly most deserving of popular support. London recently has borne a strong resemblance to a newly discovered gold field. There has been a wild rush by various syndicates to peg out their claims and to obtain concessions. In some cases there have been two or more applicants for one plot. Some of these have recognised the wisdom of combination but disappointment has been the lot of the majority Engineers, with praiseworthy anxiety to promote their own professional interests, are all on the side of the new tube railways The idea is fascinating, the opportunity is golden, no voice is heard to criticise adversely the optimistic views taken by the promoters. Indeed, when every man of any note in the English engineering world is interested in some similar undertaking, what member of their institute would be so bold as to question their proceedings ?

Impatience of control is a characteristic of those responsible for these undertakings It was stated during the proceedings in connexion with the Metropolitan District Railway Bill before a Departmental Committee that it is not the duty of any Government Department to inquire into such proposals. This formed the subject of a report by the Committee to the House of Commons which concluded thus "In view of the rapid development of such undertakings and the novel, and possibly dangerous, character of some of the proposals, the committee consider it desirable that in future every Bill containing such proposals should be reported upon by the Board of Trade " Fortunately, therefore, Parliament is able to check to some extent the exuberance of all similar undertakings. And in regard to the tube railways a debt of gratitude is due to the London County Council for the careful consideration given to the various proposals and for its able comments upon them though the fact of its harbouring rival suggestions in the form of shallow subways has in the eyes of some militated against the value of its criticism. It is the duty of all who are in any way the custodians of the public welfare and the public health to examine the various projects put forward, which does not mean that there should be any attempt on the part of municipal bodies to convert themselves into gigantic trading monopolies.

The recent developments in connexion with tube railways unforeseen or disregarded by those responsible for them do not tend to induce such implicit reliance upon the assertions of their promoters as might be desired but while railways of some sort to connect up the distant parts of the city are necessary underground railways are preferable to overhead lines as used in America. The first question, allowing their necessity is, Are deep tube lines or shallow subways the more desirable for London within a radius of six miles from Charing Cross? The difficulties attendant upon the constructing of shallow subways would of course be enormous, owing to the existence of the various connexions of house and street gully drains with the sewers. Possibly in most cases the sewers themselves might have to be diverted, together with water gas, and electric mains, while the risk of damage to adjacent property likely to arise from tunneling would be considerable and the dislocation of business enormous. In the construction of the Central London Railway at the Bank station such obstacles were, however successfully grappled with

The advantages of these shallow subways over the low level tubes to the lay mind appear to be considerable There would be economic difficulties but it is questionable if these are insuperable.[1] The accumulated sum annually spent by municipal bodies on repairs to the roads owing to continual disturbance must represent the interest on a large funded capital The same may be said of other interested companies and of the Post Office. The payment of a rental to the railway by the different bodies using the subway for access to their property should produce a large revenue while effecting a saving to each tenant. The miles of road thus rendered free for surface traffic would be very great. But the mind can hardly contemplate the dreadful inconvenience to the public, and the real pecuniary loss to the nation, that is implied in the closing for six months of such a thoroughfare as, say the Strand. This and similar things would however have to be done.

No useful purpose would be attained by discussing all of the very many schemes for tube railways submitted to the two committees presided over by Lord Ribblesdale and Lord Windsor respectively The following are only those that, having successfully passed the first stage come before the House of Commons in due course for approval or rejection. It will be a cause of satisfaction to many to know that the committees jointly contemplate the introduction of a general clause to be inserted in all Bills, dealing with every question of damage to property arising within a period of two years at least from the date of opening the lines either through "construction or working" This clause will not be retrospective in its action, and cases will be tried before a special tribunal. The committees have also exercised a wise discretion by eliminating many of the lines, evidently in the interests of the investing public. For on the continent, where electric traction has made such rapid advances, many of the leading companies have recently suffered serious depression.

It is a fact that many people do not know what lines of tube railways are projected even though their houses may be in close proximity to one of them. We will therefore begin by indicating the course taken by the various schemes which have a good chance of coming to completion First in order may be taken the District, or Yerkes, group, to be run in connexion with the Metropolitan District Railway now shortly to be electrified. It consists of the following lines run under the title of—

THE UNDERGROUND ELECTRIC RAILWAY COMPANY OF LONDON LIMITED

The Brompton and Piccadilly-circus Railway.—Authorised in 1897 with a limit of time for the compulsory purchase of land to August 1st 1900 and for the completion of works to August 1st, 1902. An extension of time was afterwards obtained to 1902 and 1904 respectively A still further extension of time is now sought to 1904 and 1906 which has been granted in committee. From the terminus at Earl's Court the line follows the existing line to South Kensington, as by an arrangement with the Metropolitan District Railway that part of their deep-level line has been transferred to the Brompton and Piccadilly Railway There is to be a generating station at Lots-road Chelsea. At South Kensington the new line will branch north east to a station in the Brompton road by the corner of Ovington square, following the Brompton road to Knightsbridge and on to Piccadilly circus, the next station *en route* being Sloane street, at which point the line comes in touch with the proposed Hammersmith and City tube line and the line from the Marble Arch to Clapham Junction The next station is Hyde park-corner Dover street, Albemarle-street, and Piccadilly-circus follow A subway will here connect this line with that of the Piccadilly and City At Piccadilly-circus a junction was proposed one branch to run under Leicester square to connect with the District deep-level at Charing Cross the other branch after crossing the Baker street and Waterloo line, and farther on the proposed Charing Cross, Euston, and Hampstead line to continue, with possibly a station in Cranbourne street, to Little Queen street, Holborn, where it would connect with the Great Northern and Strand tube running to Finsbury park. The branch line between Piccadilly-circus and Charing Cross was thrown out in committee.

The Great Northern and Strand Railway.—This tube is to start from the Crescent, now building in the Strand From here it passes under the new street and London County Council subway and then runs north across Holborn (where there is a junction) to the corner of Southampton street and Russell square. Here it bears east to the corner of Guilford street, crossing Great Coram street, Compton street, Judd street and Manchester street, where it takes a direct line to a station under the Great Northern Railway station. From here it closely follows the course of the Great Northern Railway to Finsbury park. Completion of this line is promised in about three years.

Charing Cross Euston, and Hampstead Railway.—Leaving Charing Cross this tube takes a direct line to the corner of Tottenham Court road crossing the tubes of the Brompton and Piccadilly and Central London Railways. It runs under the whole length of the Tottenham Court road and then takes a sharp curve east to a station at Euston. From here it runs directly to Camden Town to a junction at the "Mother Red Cap." One branch now bears north west for Golder's-green with stations at Chalk Farm Belsize-park, Hampstead and North End. The other line keeps due north with stations at Kentish Town Highgate-road Dartmouth park road Archway road and Highgate Archway Another extension of this line from Hampstead to Edgware has passed the committee it is not a tube line.

The Baker street and Waterloo Railway.—This tube was authorised in 1893 between these two points, though but little was done until it was financed by the London and Globe Finance Corporation in 1897 On the failure of this corporation in 1901 the undertaking was acquired by and became amalgamated with the Yerkes group. The line is now nearly half finished the tunnel being completed under the river and the line will probably be ready for traffic in about two years time. Extensions have been granted from Baker street to Paddington and from Waterloo to the Elephant and Castle. Leaving Paddington station the tube takes a fairly direct line east to the Edgware-road where it crosses the North West London tube passing to Baker street, with an intermediate station at Marylebone, in proximity to the Great Central London station. From Baker street it takes a wide curve, under Regent's park north of York terrace turning south under the Metropolitan line it runs under Portland place with a station at Oxford circus where the line crosses the Central London tube and follows the course of Regent street. There will be a station at *Piccadilly-circus* From here it runs with slight deviation to a station at Charing Cross, crossing the river west of the South Eastern railway bridge to Waterloo station thence to a station at St. George's-circus and under the London road to the Elephant and Castle.

The District Railway intends to run 12 trains per hour each way between Earl's Court and the City and six per hour from Harrow Ealing Richmond and Hounslow all passing through Hammersmith, which latter busy station will thus be provided with a most ample service. A five minute service is also promised from Wimbledon and Putney, some trains going to High street, Kensington, and others to the City The Brompton and Piccadilly line will run a 10-minute service from Earl's Court to Piccadilly circus and Finsbury park, with an all-night 15 minute service There will also be an all night 15-minute service on the District Railway No fares have yet been fixed, but it is believed that apart from the District Railway the fare will be the same throughout, the short distance paying for the long

---

[1] Roughly tube lines cost about £250 000 per mile to construct The cost of the London County Council subway now building in the new street between Holborn and the Strand is at the rate of over £340 000 per mile in a new road. This cost would be increased in running through an existing thoroughfare

It will be seen that the advantages offered by this group are very great, connecting as it does a vast network of existing rail and tramway lines hitherto isolated. The facilities offered by this system of intercommunication may help the housing problem to some extent, while the central portion of the line will unquestionably accommodate a vast quantity of midday traffic to the relief of the congested streets of business London

We next come to—

The London United, or White-Morgan, Group

This is, or was, a combination of the following proposed tubes —

Hammersmith to Charing Cross and City —Among the schemes proposed by the London United Electric Railway Company under Mr White's chairmanship was a tube line running from Barnes through Hammersmith to Charing Cross which would have competed to some extent with one of the lines of the Pierpont Morgan groups—viz, the Piccadilly and City Railway These lines have now amalgamated thus. The London United will run its proposed line only as far as Hyde park corner and the Piccadilly and City line is to continue on to Ludgate hill and the Mansion House. At the western end of the line a loop was to have been formed running up Holland park road to Shepherd's Bush, returning down the Grove to Hammersmith Broadway, thus connecting the two chief radiating points of the London United Electric Tram lines that will eventually serve a very extensive district, including Harlesden, Acton, Ealing, Uxbridge, Cranford Hanworth, Hampton, Staines, Ditton, Surbiton, Kingston, Teddington, Richmond, Wimbledon, &c The western loop from Addison road to Shepherd's Bush was very properly rejected by the committee, as it would have served no useful public purpose, while competing unfairly with the Central London line which is at present fed by the tram service at the Shepherd's Bush centre The following are the points at which it is proposed to build a station Hammersmith Broadway, Addison road, High street Kensington, Queen's gate, Sloane street (where there will be an exchange station with another line belonging to the same group running from Wandsworth to the Marble Arch, at which latter station there will be an exchange with the North West London line to Cricklewood as well as with the Central London line), Hyde-park corner, Albemarle street, Piccadilly circus, Charing Cross, Law Courts, and Ludgate-circus Here, in order to avoid St. Paul's Cathedral, the line turns south to Upper Thames-street which it follows, entering Cannon street from behind the existing Mansion House station. From Cannon street station the line is continued as--

The North East London Tube Railway —It was originally proposed to run this line to Chase Side, Southgate, but owing to local opposition the portion between Palmer's-green and Chase Side was thrown out in committee. The stations *en route* are the Monument, Bishopgate-street Without, Hackney road, Kingsland road, Stamford road, Arcola street and Church street Stoke Newington for Abney Park. At Stamford-hill the line comes to the surface. (It is in this neighbourhood that the London County Council proposes to form a working-class colony) At Church street also a branch line to the east was contemplated by the railway company but this was abandoned when the coalition took place with the now discarded City and North East Suburban line. After Church street the stations are Amhurst Park, High road, The Avenue, Lordship-lane, White Hart-lane, Chequers green, to Palmer's green. The line crosses under several existing railway lines before reaching Tottenham.

The City and North East Suburban Railway from Cannon street to Waltham Abbey also formed a part of the partnership but owing to the piece of line between Cannon street and Whitechapel having been thrown out in committee the White Morgan party dissociated themselves from the undertaking which has since been abandoned This line is an unfortunate example of the "between two stools" proverb It was originally intended to form a junction at the Mansion House station with the Metropolitan District Railway Company which was willing that the proposed tube should run for some distance under the Metropolitan line, differences arising upon financial questions coupled with the appearance upon the scene of the White Morgan combination induced the promoters of the tube line to transfer their interests to that group This was resented by the Metropolitan District Railway and the tube line was stoutly and successfully opposed.

The Marble Arch to Wandsworth Railway —This line will run from the Marble Arch in a direct line across the park to Sloane street, which is to be an interchange station with the Hammersmith and City line, passing along Sloane street to a station at Sloane square it will come in close touch with the District Railway There will be a power station at Chelsea where the line crosses the river to Battersea park. The next station will be Queen's road (Battersea), Lavender hill and Clapham Junction following

There will be some 100 miles of line in these combined railways with a service at a few minutes' interval, while the proposed fares are of a revolutionary character From Hammersmith to Charing Cross 1*d*, and from Sloane street to the City 1*d*, from Cannon street to Stamford road 1*d*, and from Seven Sisters road to Palmers-green 1*d*, while the entire journey costs 4*d* Workmen's tickets at half fares will be issued from 4 o'clock to 7 30 A M, available to return by any train during the day It is intended to introduce where possible moving platforms sloping up to the street level to supersede the use of ordinary lifts. Unquestionably this group meets the recommendation of the joint committee on tube railways last year and will materially help the solution of the housing problem, connecting as it does north east and south west suburban London with a complete net-work of tubes and electric trams In view of the enormous and increasing population in the district through which the proposed City and North East Suburban Railway was to have passed and the greatly over crowded state of the existing railway accommodation the abandonment of the undertaking is a matter for regret.

Independent Lines

The Central London Railway —Leaving the Bank station it proposes to form a loop touching Liverpool street to connect with the North London and Great Eastern stations, returning to run west *viâ* Thames street, Ludgate-circus, the Strand, Charing Cross, Piccadilly, Knightsbridge, Kensington, Hammersmith, and to complete a circle by connecting with the existing station at Shepherd's Bush. The extension from Shepherd's Bush *viâ* Hammersmith and Kensington to the City was thrown out in committee, the loop to Liverpool street has been abandoned for the present. The committee could not well have come to any other decision, considering the public advantages offered by the competing scheme put forward by the London United Electric Company The committees have been jealous of admitting any proposals where there seemed a possibility of the concessions being utilised for the purpose of blocking the route for any other line, though in this instance there was nothing to indicate such an intention Sir Benjamin Baker, the engineer of the line, in his examination in support of the proposed extension of the Central London Railway to Hammersmith, returning to the City *viâ* Piccadilly and the Strand, was evidently anxious to convert the existing shuttle service into a circle, partly in order to avoid the trains having to cross over the line at each end, in continually doing which the men, he stated, were apt to get into a kind of "penny in the-slot" method of working which did not conduce to safety

The North-West London Railway —This line was authorised in 1899 but owing to financial reasons construction has been delayed. Its promoter seeks an extension of time to complete, which has been granted by the committee. The proposed line will run from the Marble Arch through Maida vale, Kilburn, Brondesbury, and Cricklewood to Child's hill Employers of labour will be permitted to purchase workmen's tickets in bulk to dispense to their employés at 1½*d* for a single whole distance journey and 2½*d* for the double one.

The Great Northern and City Railway —Authorised from Moorgate street to Finsbury park. This line is almost completed, the stations having yet to be finished. It is the largest-sized tube yet constructed, being 16 ft. in diameter as against 11 ft. 6-in. on the Central London line. The lower portion of the tube is constructed in brickwork. It was originally intended to allow the Great Northern Company's trains to run through to Moorgate-street by changing the ordinary locomotive for a motor at Finsbury park For some reason unknown to the public this arrangement with the Great Northern Company collapsed, and the line will now be run independently as an electric railway although with the moral support of the Great Northern Company The generating station is at Pool-street on the Regent's Canal. It is the largest yet built, the engine house alone measuring 122 ft. by 52 ft. by some 60 ft. high. An extension from Moorgate-street to Lothbury was passed in committee. It is proposed to connect the Lothbury station with the existing Bank station by a subway There will be five lift-shafts sunk between the corner of the Bank and Moorgate-street with an underground station, and this has given rise to a special Bank clause for the protection of the building The next station from Lothbury will be Moorgate-street and then Old street, up to which point the tube runs in the same direction but below that of the South London line just beyond Old street the lines diverge the South London line going up the City road and the Great Northern and City line going up the New North *road to a station at Essex road, afterwards taking a direct* line through Canonbury under the North London Railway to Highbury and from there to Finsbury park. A further extension is intended to Wood Green.

The London County Council Subway for Electric Trams — This will run from Holborn to the Embankment and the tunnel will be 18 feet wide by 13 feet high. Starting from Theobalds road its course lies under the new avenue down to the Embankment, the idea being by means of proposed tramways along the Embankment to connect the present terminus of the East-End trams at Theobald's-road with the trams on the south side of the river There is, and has been a good deal said about the trams spoiling the Embankment. As a matter of fact, the road is but little used as a promenade. The place has missed its opportunities A row of good shops, with cafés, tables for coffee, chairs under the trees and a theatre would have utilised a splendid thoroughfare and relieved the Strand of its congested traffic—perhaps the cafés and theatres will come in time with the trams.

The City and Brixton Line —This is a line that has recently emerged from obscurity making a bid for popularity by assuming the seductive title of the City and Surrey Railway" It is under the guidance of Mr Harry J Lawson, and is in some way associated with the South London tube line, having received Parliamentary powers in 1898. It proposed to occupy the abandoned station of the South London line at the Monument and the tunnels in connexion under the Thames. Want of enterprise on the part of investors has blighted the earlier prospects of this undertaking A capital sum of over £1,000,000 is likely to be required but the contractors are, it seems, anxious to begin work and will start operations upon £150 000 being raised, for which they will pay interest to investors at 5 per cent. during the progress of the work. Nay more they will give a bonus to shareholders of some 17½ per cent. out of their own little profits. Parliament is to be asked to extend power to carry the line as a light railway to Reigate and eventually to the sea. This is romantic nonsense. What contract would bear profits such as would admit of 17½ per cent. being given out of them? Or how could the little station at the Monument with the small tubes under the Thames suffice for a busy local traffic and a long distance main line traffic also? The station and tubes might possibly manage the former but certainly not the latter

Such are the main schemes in course of completion. Upon the whole the committees have made a wise selection from the many projects submitted to them and have evidently looked at them, not so much from the individual as from the collective standpoint. The result should be a relief of the congested street and suburban railway traffic, a help to the solution of the housing problem, and a consequent reduction of the existing danger to health from overcrowding

The throwing out of the Bill to extend the South London" line from the Angel" at Islington to Euston is from the point of public convenience a matter for regret

In THE LANCET of May 12th 1900 *just prior to* the opening of the Central London Railway there was published an article dealing with the probable effect of the construction of the line upon the drainage of the subsoil water in its vicinity subsequent events have rather strengthened than modified the views then expressed and we refer our readers to the article in question. Our forecast was in all interested quarters described as an unwarranted attempt to scare the public, so that no one need be surprised to find our view largely confirmed by subsequent events. In the discursive remarks that follow upon certain details in the construction of tube railways—especially in regard to the prevention of accidents and of nuisance from vibration and the provision of proper ventilation—it will be seen that upon the whole we take a cheerful view of the undertakings But the public is much more awake now than it was two or three years ago to the inconveniences and risks that may counterbalance the advantages of underground travelling

The questions connected with the construction of the proposed lines are of such a highly technical nature that no one but an engineer would venture upon technical criticism, but criticism is not valueless because it is not technical Into the respective merits of a three-and a half or four and a half chain curve it is impossible, for example, for us to enter but it must be evident to the least initiated that a train running at a high rate of speed down a gradient such as, say from Piccadilly to Charing Cross, and making *too sharp a turn round to the Strand* at the *bottom of the* hill, stands some extra chance of being derailed in the case of the sharper curve.

Diameter of the tube —There exists some diversity of professional opinion as to the desirability of using tubes of 11 feet and six inches in diameter as at present in use on the Central London line, or of 13 feet and six inches, the minimum size suggested by Colonel Yorke, electrical adviser to the Board of Trade, who holds strongly to this opinion. The latter size greatly increases the cost of construction. Mr Brereton Sir J Wolf Barry's partner as engineer to the proposed Brompton and Fulham line, estimates the cost of a tube of 11 feet and six inches on his line at £40 per yard, and of a tube of 13 feet and six inches at £48 per yard, but the larger tube has the advantage of permitting the use of the ordinary railway rolling stock, while giving greater facilities for repairs to the lines, which is important in the case of all night services and for the exit of passengers in the event of a breakdown. There would seem also to be another important advantage that relates to ventilation

Ventilation.—Should a serious breakdown occur the probability is that between the stations most widely apart there would be two trains in the tunnel at one time. In the smaller tube the circulation of air would then be greatly impeded. It has now been generally admitted that the hopes of the engineers as to the ventilation of the tunnels by the passage of the trains have not been realised and efforts are being made on the Central London line to accomplish this at night by a process of exhaustion. This considering the numbers carried, must be quite inadequate to the requirements. At present it is very noticeable how large a proportion of the passengers are affected by the influence of an excessive quantity of carbonic acid gas associated with other human exhalations. What might result from a prolonged exposure in the event of a serious accident is not pleasant to contemplate. There have been one or two fatal cases in which people have fallen upon the line from some cause not very clearly defined. It is understood that the Great Northern and City railways will have a continuous current of fresh air admitted at some point between each station. This in conjunction with the large size of the tube should give very good results

Both Mr Yerkes and Mr Perks (the chairman of the Metropolitan District Railway) in giving evidence on the tube lines connected with the District Railway undertook to change the air of each mile of tube every 45 minutes presumably by a *system of fans. The difficulty in* the existing lines is no doubt greatly increased by the continued action of the lift which are constantly reversing the draught. Colonel Yorke would wish the fans to be driven by some other motive power than electricity so that in the event of any breakdown in the electrical arrangements the fans would still continue to work.

Accidents —Much has been said in committee as to the desirability of side doors to the cars and side tunnel platforms for use in any emergency The opinion expressed by Mr Yerkes is that they would tend to disaster during a panic. In the event of an accident that is quite conceivable Doors at each end of the train with a centre platform are suggested in preference but should a train be derailed collide with the sides of the tube few, if any, of these doors would open. It would be one more chance in the passenger's favour when the train was on fire if all such doors were skeleton ones filled in with some fabric which could be easily cut through with a penknife. The minds both of Mr Yerkes and Sir Alexander Binnie are exceedingly receptive to fresh opinions and this, though excellent in its way, makes their views sometimes difficult to follow Sir Alexander Binnie, for instance, last year gave evidence that confluent junctions were things to be avoided, but in his recent examinations his evidence seemed to be entirely in their favour, possibly Mr Yerkes may have succeeded in convincing him of his former error Mr Yerkes, again, stated that at one time he was satisfied that a tunnel of 11 feet and six inches was too small and that there ought to be a footway at the side of the train, he is, we believe, now convinced that for safety one of 11 feet and six inches is the best. The reason which he gave was that in the case of the train being derailed a side platform would be swept away, but he proposed to put a centre platform, though what was to prevent this being swept away also he did not state Sir Douglas Fox, engineer to the North East London Railway, is in favour of the side platform, under which he proposes to place the conductors Some kind of platform is necessary as it might be required for use in the event of a breakdown The possibility of a fracture in the tube itself admitting water and thus setting up electrical connexion between the wreckage and the broken cables underlying the fractured platform might form an unpleasant feature in an accident. In a recent case at the West End of London the accidental fracture of a water main resulted in the setting up of a short electric circuit in one of the public supply cables, the effect of which was to boil the escaping water in the short space of time that elapsed between the accident and the fusing of the cut-out on the cable It would seem within the bounds of possibility that side guide wheels might be used in the smaller tube, thus lessening the chance of derailment and perhaps permitting the use of increased speed

The London County Council and Colonel Yorke (on behalf of the Board of Trade) wisely advocate the lighting of the tunnels It is to be hoped that the current supplying such lights will be generated and conducted by a system entirely independent of that supplying motive power as will be the case on the Great Northern and City line The same may be said of the signals

Vibration.—The bitter complaints of the nuisance due to vibration made by a section of the public dwelling above the course of the Central London Railway have roused the strongest opposition on the part of those likely to be affected by the proposed new lines. In a discussion on a paper read at the Auctioneers' Institute in December last by Mr G M Freeman, K.C, Mr Minshall maintained that one cause of the vibration on the Central London Railway arose from the gauge being six inches too narrow In the experiments conducted by Lord Rayleigh's committee the trains made up upon the multiple unit system, first used by Mr Frank Sprague of New York, were found greatly to reduce the evil, though the extent to which this was successful upon the line in question has been variously estimated. The promised immunity from vibration seems to depend upon the fulfilment of several conditions First, upon a more equal distribution of weight hroughout the length of the trains The heavy, almost pringless engines, weighing possibly some 40 or 50 tons, are o give place to light spring motor cars alternately coupled ith ordinary cars or trailers upon the multiple-unit system use on the American elevated lines Another condition the character of the rails used and the method adopted for ing them. The rails in use upon the Central London line ere vibration has been most pronounced, are bolted ctly on to the sleepers through the broad bottom web he rail, each rail, however, being independent of its hbour The form of rail now proposed differs in section this last and is attached to the sleepers by chairs while also bolted to the adjoining rail with fish plates, the hus forms one continuous whole This avoids the jerk the depression of each rail as the engine passes from the other A third condition is sinking the tubes to a depth This last may minimise the intensity of any ent but will probably ext the area over which it felt

isk—It is to be any calamity similar to orable accident on the iverpool Overhead Railway will be avoided by the adoption of precaut of which the sad loss of life on the L be attributed. Colonel Yorke, in his evi Windsor's committee anticipated little dif against this evil if the use of wood w cables and electrical machinery, or if, were protected by some non-combustible n he advocated the general use of non comb for all trains, stations, signal cabins, a sunk buildings If wood must be use owing to their lessening vibration they creasoted but rendered non-inflammable by Mr Yerkes informed the committee was in t Compressed asbestos will probably take the lighter woodwork. This is all very satisfac goes well, but in the event of an accident the ponents of a carriage will be apt to rearrange th live cables may form unexpected connexions. against fire the forced draught which it is now use for ventilating the tunnels will always driv in one direction, which is a factor worthy of cons providing means of exit in such an event.

Mr Yerkes's opinion is that the safest place for in the event of an accident is the carriage in w seated and he deprecates the use of the larger a tube with the side platform and side exits from the conducive to panic, and, generally speaking, perh right, but should the train catch fire and there be exit available at the end a ghastly holocaust woul while the panic would be too awful to contemplat smoke from creasoted sleepers might in such a case merciful deliverance from suffering

THE ANNUAL REPORT OF THE MEDI OFFICER OF THE LOCAL GOVERN MENT BOARD FOR THE YEAR

1900–1901[1]

FIRST NOTICE.

THE annual report of the principal medical officer of Local Government Board is a volume the publication of whi is looked forward to with interest by our readers, for it always certain to contain a very large amount of informatio in regard to the present sanitary state of England and the means which are being adopted for the improvement of the existing conditions In addition to this it gives an account of what is being done by means of careful laboratory experiments to elucidate points about which we are still in ignorance in regard to the etiology, and the prevention of disease. It can be said without boastfulness that no other country has produced so valuable a collection of works bea ing on questions of public health as this series of annu reports, the first of which was published in the year 1870

The present volume differs in no important point from it immediate predecessors and the arrangement of the contents is identical with that which was followed in previous years. The report of the principal medical officer, Mr W H Power, occupies no more than 26 pages and it serves as an introduction to the record of work done by the officers in his department, summarises the conclusions which they have adopted as a result of their inquiries, and emphasises the points which are particularly worthy of note in the year's work. The chief points to which attention is called are arranged under the headings Vaccination and Public Vaccination (p ix.), General Administrative Business of the Medical Department (p. xi.), the Distribution of the Plague and the Precautionary Measures adopted in the Country in view of its Advent (p xix.), and Scientific Investigations made by Officers of the Board (p. xxii.)

Several of the experienced members of the medical staff of the Local Government Board have recently been employed on work not directly connected with the department, to which, therefore, their services have for the time in great measure been lost. Dr H. F Parsons, whose special report some 12 years ago on the influenza epidemic was of its kind a perfect piece of work, has been appointed a member of the Departmental Committee to inquire into the organisation and staff of the Geological Survey Dr H. T Bulstrode was appointed a member of the Departmental Committee on Food Preservatives. Dr Theodore Thomson has been engaged on a special inquiry into the sanitary state of Dublin, an investigation undertaken at the instance of the Lord Lieutenant of Ireland. Mr Power as a member of the General Medical Council appointed by the Crown has also had some of his time occupied by attending the deliberations of that body so far as his office duties have permitted. The way in which the services of these medical officers have been sought to carry out duties not strictly within their province shows that their abilities, their industry, and their training are appreciated when serious work is wanted.

---

[1] Thirtieth Annual Report of the Local Government Board, 1900-1. Supplement containing the Report of the Medical Officer for 1900-1. London: Eyre and Spottiswoode 1902. (Cd 747 Price 6s)

The report of the principal medical officer is followed by three appendices. Appendix A contains a digest of the vaccination officers returns with regard to children whose births were registered in the year 1898, together with five other reports concerning vaccination (pp. 1 to 60) This is followed by a summary of the work of the medical inspectors during the year 1900 (p. 61)—an abstract of medical inspections made in 1900 with regard to the incidence of disease in particular places and to questions concerning local sanitary administration (p. 67). A series of special reports made by Dr S Monckton Copeman (p. 77) Dr R. J Reece (p. 98) Dr S. W Wheaton (p. 113) Dr F St George Mivart (p. 126), Dr R. W Johnstone (p 149) and Dr E. Petronell Manby (p 165) respectively serve to show the manner in which the work of local inspection is carried out. Statistical details are given in regard to certain notified infectious diseases in 94 urban districts quarter by quarter and for the whole year 1900 (p. 176), and similar details are given in regard to each of the sanitary areas within the administrative county of London and in the county as a whole week by week, quarter by quarter, and for the whole year 1900 (p. 186)

The memoranda prepared or revised in the medical departments during 1900 are printed *in extenso* (pp. 228-257) Of these memoranda there are seven 1. On the Provision of Isolation Hospital Accommodation by Local Authorities revised August, 1900 This is a most useful document, clearly written and illustrated by plans showing how such hospitals should be built. 2. Plague Memorandum prepared September 1900 This memorandum deals with (i.) administrative considerations (ii.) symptoms of plague (iii.) directions for the use of the Haffkine plague prophylactic (iv.) directions for obtaining and forwarding for bacteriological examination material from suspected plague cases from the living person and from the dead body (v.) a general memorandum on the proceedings which are advisable in places attacked or threatened by epidemic disease (vi.) a memorandum as to the annual reports of medical officers of health (London) and an extract from the Order of the Local Government Board dated Dec 8th 1891, on the duties of a medical officer of health as regards the district or part of a district for which he is appointed and (vii.) a memorandum as to annual reports of medical officers of health in the provinces and an extract from the Order of the Local Government Board dated March 23rd 1891 as to the duties of a medical officer of health. These two last-mentioned memoranda should prove of great use Many medical officers of health especially in rural districts have entered upon their duties without having had much previous knowledge of or special training in matters pertaining to public health, and a considerable proportion of those living in the country have consequently been somewhat at a loss to understand what their exact duties are The memorandum will be of the greatest service to these officers, for it deals not only with the nature of the duties which they are called upon to perform, but gives admirable directions as to the best mode of doing them.

A report by Dr Parsons on Geological Considerations in relation to Public Health and Sanitary Administration (p 258) is a useful result of his investigation of the Survey Department, for it shows conclusively and in a short space the very great practical importance of geological conditions in their bearing on hygiene.

The two next appendices are the work of Dr R. Bruce Low Of these the first gives a summary of the Progress of Diffusion of Plague in 1900 (p. 264) and the second is a memorandum on Plague in England and Wales during 1900 and on certain precautionary measures employed to prevent the importation and spread of the disease (p. 283). These reports necessarily lose some of their interest from the delay which has occurred in their publication, for it already seems quite ancient history to recall the plague visitation of 1900 The scare which generally affected the inhabitants of the English seaports has not been without its uses for it has undoubtedly led many of the port sanitary authorities to effect improvements which without the spur of some unusual excitement might have been longer delayed. The last report of the series, which is by Dr Thomson gives an account of the general sanitary administration in some of the ports and riparian districts (p. 294) and as a result of his very careful investigation it is evident that many of the places which he visited were and some probably still are, in a state which reflects great discredit on the local sanitary authorities.

The second appendix (Appendix B p. 295-581) contains the reports of special investigations undertaken to determine some points in regard to the spread of preventable disease There are in all eight reports which show the results of the work done by Dr E Klein, Dr A. C Houston, Dr M H Gordon Dr Sidney Martin, and Dr J S. Haldane. The questions dealt with include studies on the spread of disease by means of certain articles of food, a report on the bacteriology of scarlet fever a note on the destruction of rats on board ship, and an important series of investigations dealing with the inoculation of soil with sewage, the nature of the antagonism of the soil to the typhoid bacillus and on the chemical and bacteriological examination of the water of Chichester Chichester it will be remembered, is a city which for years has supplied a constant field for the study of the etiology of typhoid fever and has already engaged the attention of more than one member of the Medical Department of the Local Government Board.

The third appendix (Appendix C p. 609) contains reports by Dr F R. Blaxall Mr H S. Fremlin, and Dr Alan B Green on research work in connexion with glycerinated calf lymph. Mr Power in his introductory remarks to this part of the work of his medical staff explains that they habitually test the efficiency of the glycerine process as used at the lymph laboratories for the purpose of eliminating from the successive series of lymphs which are undergoing the process of maturation those extraneous micro-organisms which are commonly associated with lymph as collected from the calf They have also done much work in gaining a knowledge of the bacteria of vaccine lymph and of the methods necessary for the detection the isolation and the identification of these organisms They have closely studied the condition of lymph glycerination. Finally they have searched for agencies other than glycerine more competent than that medium to eliminate from the lymph extraneous micro organisms and free also from that ultimately deleterious effect on the activity of vaccine which is apt to result from long sustained association of the lymph with the glycerine" (p. xxxiii.)

In their reports Dr Blaxall and Mr Fremlin refer to the Report of THE LANCET Special Commission on Glycerinated Calf Vaccine Lymphs[1] (pp. 610 611 610) with the results of which they are not in accord The experiments which they have carried out and of which details are given lead them to believe 1. That glycerinated calf lymph contains no organisms which can be described as anaerobic—that is none which are capable of growth under strict anaerobic conditions and incapable of growth under aerobic conditions 2. That all the extraneous organisms are facultative anaerobes, that is can grow under either aerobic or anaerobic conditions, with the single exception of bacillus subtilis which is well known to be an obligatory aerobe. 3. That the extraneous organisms grow equally well under aerobic and anaerobic condition in equal numbers and with colonies of similar appearance, with the exception that under anaerobic conditions produced by hydrogen the development of definite pigments is to a large extent lost 4. That glycerinated calf lymph contains no spore-bearing organisms, aerobic or anaerobic capable of growth on the various media used, other than the members of the mesenteric group commonly met with. 5 That in glycerinated calf lymph there are frequently present bacilli which often escape notice in ordinary plate cultivations They are usually few in number and probably occur only in the original plate where many colonies being crowded together and more or less ill developed they have no opportunity of displaying their characteristic forms and consequently are missed But these bacilli which belong to the proteus group, and very closely resemble proteus vulgaris, when placed in suitable media such as beef broth, and cultivated either aerobically or anaerobically, grow luxuriantly and multiply much more rapidly than do the staphylococci

---

[1] THE LANCET, March [illegible]

Dr Blaxall has made a series of experiments on the effect of heat on the activity of crude calf lymph and on the contained extraneous organisms which it contains The results of his investigation, he believes, show (1) that it is possible for the vaccine organism to withstand a comparatively high temperature 57 5° C, for five minutes without loss of potency, (2) that the lethal point is a very exact one—all the lymph gave good results after exposure for five minutes to a temperature of 57 5° C, and all failed entirely after exposure for the same time to a temperature of 60° C (at 58 5° C only a feeble result was obtained or none), and (3) that there appears to be, on the part of the vaccine organism, a greater power of withstanding the effects of high temperature than that possessed by the extraneous organisms

Dr Alan B Green has made a series of experiments on the disinfectant action of chloroform and of various other substances on the specific and extraneous organisms of vaccine (pp 639, 663) The conclusions at which he has arrived are that the "specific vaccine virus can withstand the action of several substances besides glycerine which kill in part or wholly the extraneous organisms, in other words, that these substances appear to have a selective germicidal action on the micro-organism of crude calf lymph Of these substances chloroform employed in a saturated watery solution is the most important. Under its action the extraneous micro-organisms of crude calf lymph have been, as a rule, eliminated in from 24 hours to seven days, and the specific organisms have survived in every case as long as have the specific organisms in the glycerine "control" experiments, and in some cases for a longer period The experiments which have shown these results have up to the present time not been very numerous (20 or 30 in all), and Dr Green advises that his investigations should be continued as there is *prima facie* evidence that the use of chloroform in the preparation of vaccine might prove of considerable value Mr Power is evidently impressed with the importance of this research, for he concludes his report by commenting on it in terms full of hope "It affords prospect," he says, "of an agency in lymph manufacture not only more potent than glycerine as a germicide of extraneous micro-organisms but also considerably less deleterious than that substance in later antagonistic influence on the activity of the vaccine lymph after it has passed from the Board's establishment into the hands of the public vaccinators"

ARMY MEDICAL REPORT FOR 1900[1]

CONCLUDING NOTICE.[2]

CONFINING our attention to a few of the statistical results and salient points of this report we are glad to notice that, taking all forms of venereal diseases together, there was a decline in the ratios for 1900 among the troops serving in the United Kingdom as compared with those of the year before and with the average of the preceding 10 years

The number of invalids discharged the service in the course of the year 1900 on account of medical unfitness for further service was 5074, which gives a higher ratio per 1000 than in the previous year or than the average for the preceding 10 years This number includes 475 men who had returned from the South African field force invalided for disabilities contracted in the campaign. The full statistics, reserved for record at the conclusion of the war, ought soon to be in our hands Among the officers serving at home, whose average strength is given as 1329, we note that there were 16 deaths, giving a ratio of mortality of 4 0 per 1000 Influenza caused 260 admissions (one fatal) and there were five cases of enteric fever (1 2 per 1000) and no deaths

The average strength of women borne on the army in the United Kingdom in 1900 was 9148, of whom 53 died The ratio of sickness among them was 428 0 per 1000, and that of mortality 5 79, in both respects somewhat higher than in the returns for the previous year The average strength of the children borne on the army at home in 1900 was 18,156, with a sick-rate of 560 8 and a death rate of 20 82 per 1000, in both respects also somewhat higher than for the preceding year

As regards recruiting, we learn that the total number of recruits inspected during the year was 84 402 Of these 23 105 were rejected as unfit Including, however, those subsequently discharged within three months as unfit for service the total number of rejections equalled 23,745, or a ratio of 281 33 per 1000 The facts connected with recruiting and the causes of rejection are set forth as usual, with much laborious detail

There is nothing that strikes us as particularly new in the reports on the sanitary conditions of the different military districts and stations of the United Kingdom. At Golden Hill Fort Isle of Wight, we notice that a septic tank system of sewage disposal has been installed and has been in use for about a year at Warden Battery It is said to have required little or no attention. At Netley it is reported that defects were discovered in connexion with the flushing of the water closets, the fittings and pipes of which were destroyed by the chlorinated water produced by the Hermite process At the Royal Military Academy, Woolwich, it is remarked that two large corrugated iron huts had been erected to afford increased hospital accommodation and the need of another similar hut for infectious cases had been represented (Is there not accommodation available for this purpose at the Herbert Hospital?) Passing over the Mediterranean stations and coming to the sanitary report for Bermuda we notice that the main feature of the decline of enteric fever at that station is its coincidence with the gradual replacement of the dry earth system conservancy by a water carriage system The need of a destructor for burning ashbin refuse and the provision of a modern and efficient disinfector for hospital use are pointed out. We have already touched upon Mauritius, but seeing that plague occupies a place in the public health returns received from this colony, we may add that the town of Port Louis is stated to be insanitary, the barracks are old fashioned, defective, and unsuitable, and the surroundings are objectionable. According to the report the town is saturated with the filth of ages and badly drained The soldier is the chief sufferer, as his residence there is at present compulsory Both sick and and non effective ratio would, it is alleged, be surprisingly reduced if Port Louis ceased to be occupied altogether or if its garrison were reduced to the utmost possible extent.

It will be remembered that a large number of Boer prisoners of war were deported to Ceylon Two large camps, the report tells us, were established for them at Diyatalawa. The sanitary arrangements of these camps were carefully worked out with most satisfactory results

Passing on to the long and elaborate report "on the health of European troops serving in India," we find that during 1900 there was a decrease of 7144 in the strength of these troops as compared with 1899, mainly caused—but not entirely for there were other contributory causes—by the non replacement of the troops sent to South Africa in that year

The following table shows the admission, death, invaliding, and constantly sick rates among the troops in India during 1900 —

Average strength for 1900	Admissions	Deaths			Invalids		Average constantly sick	Ratio per 1000 of strength.				
		In the command	Of invalids	Total	Sent home	Finally discharged		Admissions	Deaths	Invalids sent home	Invalids finally discharged	Constantly sick.
60 553	69 225	885	45	930	2026	677	4 342·21	1 143 2	15 36	33 46	11 18	71·71

As regards enteric fever, the most notable fact about it is the decrease in the prevalence of this disease among the troops in 1900—a decrease in the average number of men constantly sick, which, as compared with the preceding year amounts to 72.50. At page 153 of the report there is a table which sets forth the results in figures of enteric fever in 1899 and 1900 respectively. It is well known what a terrible scourge this fever has for many years past proved to be to the British army serving in India, and as far as the mortality is concerned enteric fever in 1900 still gave rise to 32.65 per cent. of the total death-rate from all causes as compared with 40.37 per cent. in 1899. Statistically speaking, however, there was a great diminution in the admission and mortality ratios for enteric fever in the Bengal and Punjab commands, though the case-mortality was high, being 29.8 per cent. of those attacked. The admission and mortality rates for 1900 are both lower than for any year since 1888. The disease was general and not confined to particular stations. A severe outbreak at Quetta was the chief cause of the increased admission and mortality rates in the Bombay command. While the decreased number of admissions for enteric fever in India during 1900 is mainly, as well as in our opinion rightly, attributed at page 159 of the report to the suspension of the trooping system and the consequent absence of drafts of specially susceptible material, it is nevertheless right to add that this fact does not wholly account for the decreased prevalence of enteric fever. Reasons are assigned for believing *that the decrease was partly due to more satisfactory causes* than the absence merely of susceptible men. Almost all the points connected with the causation of enteric fever in India are noticed. The exhaustive and carefully considered article by Major T. O. McCulloch, R.A.M.C., on Enteric Fever amongst the British Troops in India, published in the Appendix, should be read in connexion with this subject. What he adduces in regard to the relative prevalence of this fever in the cavalry as compared with other arms of the service is new and interesting. Munson in his work on "Military Hygiene" has also pointed out the much greater prevalence of enteric fever among the cavalry of the United States Army.

[1] Army Medical Department Report for the year 1900 with appendix Vol XLII London Printed for His Majesty's Stationery Office by Harrison and Sons St. Martin's lane Printers in-ordinary to His Majesty 1902. Price 2s 3d.

[2] The first notice was published in THE LANCET of August 9th, p 398

One thing seems to us quite clear—namely, that we are still far from having exhausted all the points connected with the etiology and causation of typhoid fever in armies. It is all very well arbitrarily to take up some one particular view and, because it can, for instance, be shown to be a water-borne disease, to say that *that* is the sole and exclusive source of its spread, but is it the correct view? There are too many *people who simply* content *themselves with mentally affixing* "water-borne" to this form of fever as if it were a label which both described its nature and causes and the only vehicle through which its infection was spread. No account is taken of the influence of direct infection, fouled soil, dust storms, and insectivorous agency in the spread of the disease in tropical and sub-tropical climates. Sir William Taylor, when principal medical officer in India, was simply repeating the results of the previous experience of others when he reported in 1898, "The liability of troops on service to enteric fever, even when encamped on what appears to be virgin soil, is a fact in regard to which almost all observers are unanimous, and a considerable part of the increase in both the admission and mortality rates for 1898 can be accounted for by field service." He goes on to say that the disease is endemic in most military stations in India, that cases may come from all parts of barracks, and that even when it assumes an epidemic form it is often impossible with any degree of certainty to trace the disease to specific contamination of water, milk, *food*, or *air*, and *he adds that the enteric* fever bacillus may be more widely distributed than our present knowledge leads us to suppose. We know much more now than we did about the length of time during which the typhoid bacillus may remain in the tissues of the body whilst still retaining its potential activity, and more also about the conditions under which the bacillus can exist outside the body. The part which the urine may play in the spread of infection is also a very important and persistent factor which has not been, and is not even now, sufficiently taken into account. It is in all probability a fertile means of spreading the disease, seeing that the specific bacilli are often to be found in it in enormous numbers. We have in the previous article called attention to the exhaustive and elaborate Report of the Commission on the Typhoid Fever Epidemics in the Camps of the United States Army in 1898. Ample opportunities were afforded to the commission owing to the widespread prevalence of this fever (more than 90 per cent. of the regiments developed typhoid fever within eight weeks of going into camp) for going into the whole subject from a many-sided and all-round point of view. The commission certainly seems to have spared no pains in order to discover the origin of the disease and to trace out the various ways and channels by which the infection was spread in the various encampments. But our great point in calling attention to this American report is, as we have already said, its very important bearing and the new and strong light which it throws on the typhoid fever of armies. The causation of this disease is *the* question of the day for the army sanitarian.

Among the articles in the Appendix many call for notice which only want of space prevents us from giving, but we must call attention to the report on the Progress of Hygiene for the year 1900–1901, contributed by Major R. H. Firth, R.A.M.C., the present professor of military hygiene at the Army Medical School, Netley. It is an excellent and most useful record, the materials for which have been judiciously selected and put together and commented upon in an interesting and instructive way. This is followed by a report giving a list of operations at the Royal Victoria Hospital in 1900–1901, with notes on some of the operation cases and remarks on some of the work done in the surgical division, by Major W. Dick, R.A.M.C., the assistant professor of military surgery. In the *Appendix will also be found the first annual report of* the Pasteur Institute in India by Major D. Semple, R.A.M.C., the instructions concerning army railway ambulance carriages (with diagram), and the tables showing the results of preventive inoculation against enteric fever during 1900. These tables and the remarks submitted by the principal medical officer of India on the figures connected with the inoculations in that country are somewhat intricate and do not readily lend themselves to any brief statement and analysis.

Public Health and Poor Law.

LOCAL GOVERNMENT BOARD

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF *THE LOCAL GOVERNMENT BOARD*

On Prevalence of Throat Illness in and near the Ditcham Park Estate in the Catherington and Petersfield Rural Districts of Hampshire,[1] by Dr. L. W. DARRA MAIR.—Small outbreaks of infectious disease in sparsely populated districts are worthy of careful study from the view-point of epidemiology. In such circumstances it is often possible to trace infection to a common cause or causes with greater certainty than in populous neighbourhoods. Dr. Mair's report deals with "throat illness" which prevailed between April and August of last year among the inhabitants of some 20 dwellings scattered about the Ditcham Park Estate in Hampshire to an extent which caused the owner of the estate to make a strong appeal for inquiry to the Local Government Board. The illness was in different instances diagnosed as scarlet fever, diphtheria, and quinsy. Excluding two doubtful cases 22 persons living in 10 houses were attacked during the period. In several the illness was severe, and two cases were fatal.

Dr. Mair devotes the greater part of the report to a statement of the information which he *obtained from medical* practitioners concerned and from personal inquiry of the inhabitants at each of the dwellings affected. He then sums up the evidence and concludes that two distinct infections were operative, scarlet fever with distinctive rash which attacked six cases in two dwellings, and "sore throat illness," without scarlatinal rash, which attacked 16 cases in eight dwellings. Scarlet fever without rash is not uncommon, but, as Dr. Mair points out, if the disease in these eight houses had been scarlet fever it is most improbable that no rash would have been manifested in any of the 16 cases. Moreover, all the eight households concerned contributed children to the small school which serves the estate and which afforded several opportunities of infection, whereas the two scarlet fever households had no relation with this school. The evidence that the "sore throat illness" was diphtheria, however, had a good deal in its favour, particularly the fact of the severity of the illness in some cases and the occurrence of two deaths out of the 16 On the other hand, no diphtheria bacilli were found in single specimens of throat swabs from two cases taken at the end of the epidemic

---

[1] London: Eyre and Spottiswoode, East Harding-street; [illegible] Oliver and Boyd; Dublin: E. Ponsonby. Price 3d.

The interest of these observations lies in the fact that the introduction of these illnesses at Ditcham Park can be referred with a considerable degree of certainty to a single case A family named Case went from Portsmouth to live at Ditcham Park on April 11th, leaving at Portsmouth Isolation Hospital a child suffering from scarlet fever. This child left hospital and went to her new home on May 23rd. A week before, May 17th, her convalescence had been interrupted by a slight attack of adenitis, and about that time several cases of post-scarlatinal diphtheria had occurred in the hospital The circumstantial evidence which suggests that the return of this child was the starting point of both infections in Ditcham Park, the scarlet fever series and also the "sore throat" series, is fairly strong, and in Dr Mair s view an assumption that on discharge from hospital this child not only retained scarlatinal infection (in other words, was capable of producing the familiar "return case") but also retained 'infectious sore throat," or diphtheria, infection, would afford a consistent explanation of a sequence of events not otherwise easily capable of elucidation. Dr Mair refers, however, to two elements of uncertainty one that the other Case children, all of whom had previously suffered from scarlet fever, developed neither scarlet fever nor "sore throat illness" on return of their sister, and the other, that in the scarlet fever series the possibility of infection through washing scarlet fever infected clothes brought from Portsmouth to Ditcham could not be altogether excluded. In this connexion he criticises the practice adopted at Portsmouth of making a charge of 5*s* and upwards for disinfection of bedding and clothing from infected premises The report as a whole affords a suggestive contribution to the difficult question of "mixed infections"

VITAL STATISTICS

HEALTH OF ENGLISH TOWNS

IN 76 of the largest English towns 9568 births and 4419 deaths were registered during the week ending August 16th The annual rate of mortality in these towns, which had been 14 1 and 13 6 per 1000 in the two preceding weeks, rose again last week to 15 5 per 1000 In London the death rate was 15 8 per 1000, while it averaged 15·4 in the 75 other large towns. The lowest death rates in these towns were 5 6 in Handsworth, 7 6 in Bournemouth and in Wolverhampton, 8 0 in Warrington, 9 0 in Hornsey, 9 7 in Southampton, 9 8 in Tottenham, and 9 9 in Plymouth and in Stockport, the highest rates were 19 4 in Gateshead, 19 5 in Wigan and in Middlesbrough, 19 7 in South Shields, 21 3 in Liverpool, 20 2 in Tynemouth, 22 2 in Stockton-on-Tees, and 22 3 in Wallasey The 4419 deaths in these towns last week included 642 which were referred to the principal infectious diseases against 552, 579, and 584 in the three preceding weeks, of these 642 deaths 245 resulted from diarrhœa, 114 from measles, 104 from whooping cough, 70 from diphtheria, 52 from scarlet fever, 48 from "fever" (principally enteric), and nine from small-pox. No death from any of these diseases was registered last week in Hornsey, Hastings, Southampton, Great Yarmouth, Handsworth, Smethwick, Bury, Newport (Mon.), or Swansea, while they caused the highest death-rates in West Ham, Norwich, Bristol, Hanley, West Bromwich, Bootle, and Rhondda The greatest proportional mortality from measles occurred in West Ham, Bristol Walsall, Stockton on Tees, West Hartlepool, Gateshead, Cardiff, and Rhondda, from scarlet fever in West Bromwich and King's Norton, from diphtheria in Willesden, from whooping cough in Leyton, Portsmouth, Norwich, and Birkenhead, from "fever" in Grimsby and Rhondda, and from diarrhœa in Reading, Norwich Bootle, St. Helen's, and Rhondda. Nine fatal cases of small pox belonging to the 76 large towns were registered last week, of these, five belonged to London and one each to West Ham, Leyton, Walthamstow, and Liverpool There were 170 small-pox patients under treatment in the Metropolitan Asylums hospitals on Saturday, August 16th, against numbers declining from 1515 to 239 on the 16 preceding Saturdays; 24 new cases were admitted during the week, against 23, 44, and 21 in the three preceding weeks. The number of scarlet fever cases in these hospitals and in the London Fever Hospital, which had been 2486, 2562, and 2591 at the end of the three preceding weeks, had further increased to 2595 at the end of last week, 303 new cases were admitted during the week, against 397, 382, and 295 in the three preceding weeks The deaths referred to diseases of the respiratory organs in London, which had been 128, 135, and 131 in the three preceding weeks, rose again last week to 159, and were 8 above the corrected average number The causes of 41, or 0 9 per cent., of the deaths in the 76 towns were not certified either by a registered medical practitioner or by a coroner All the causes of death were duly certified in Bristol, Nottingham, Salford, Bradford, Newcastle, and in 47 other smaller towns, the largest proportions of uncertified deaths were registered in Norwich, Hanley, St Helens, Preston, and South Shields

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16 6 and 13 9 per 1000 in the two preceding weeks, rose again to 15 7 per 1000 during the week ending Saturday, August 16th, and exceeded by 0 2 per 1000 the mean rate during the same period in the 76 large English towns The rates in the eight Scotch towns ranged from 11 9 in Leith and 14 1 in Dundee and in Perth to 19 2 in Paisley and 21 2 in Greenock The 507 deaths in these towns included 25 which resulted from whooping cough, 23 from diarrhœa, nine from measles, five from "fever," one from scarlet fever, and one from diphtheria, but not one from small-pox. In all, 64 deaths resulted from these principal infectious diseases last week, again 48 and 46 in the two preceding weeks These 64 deaths we equal to an annual rate of 2 0 per 1000 which was 0 3 p 1000 below the mean rate last week from the same diseas in the 76 large English towns The fatal cases of whoopin cough, which had been seven and 16 in the two precedi weeks, increased last week to 25, of which 14 occurr in Glasgow, five in Aberdeen, two in Edinburgh, two Dundee, and two in Leith The deaths from diarrhœ which had been 21, 19, and 16 in the three precedi weeks, rose again to 23 last week, and included 11 Glasgow, four in Aberdeen, three in Edinburgh, two Dundee, and two in Leith The fatal cases of measle which had been 12 and five in the two preceding week increased again last week to nine, of which five were regi tered in Paisley, two in Glasgow, and two in Edinburg The deaths referred to different forms of "fever," which ha been three and four in the two preceding weeks, further ro to five last week, and included two in Glasgow and tw in Edinburgh The deaths referred to diseases of th respiratory organs in these towns, which had been 80, 7 and 63 in the three preceding weeks, rose again la week, and were 20 in excess of the number in the co responding period of last year The causes of 17, or mo than 3 per cent, of the deaths registered in these eight town last week were not certified.

HEALTH OF DUBLIN

The death rate in Dublin, which had been 21 2 and 20 per 1000 in the two preceding weeks, futher declined to 19 per 1000 during the week ending August 16th. During th past four weeks the death rate has averaged 20 3 per 1000 the rates during the same period being 14 2 in Londo and 15 6 in Edinburgh The 142 deaths of person belonging to Dublin registered last week showed a decline of five from the number in the preceding week and included 24 which were referred to the principal infectious diseases, against 15, 29, and 30 in the three preceding weeks, of these 20 resulted from measles, two from "fever," one from scarlet fever, and one from diarrhœa, but not one from either small pox, diphtheria, or whooping cough These 24 deaths were equal to an annual rate of 3 3 per 1000, the mean death rate last week from the same diseases being 3·0 in London and 1 5 in Edinburgh. The fatal cases of measles, which had been eight, 18, and 20 in the three preceding weeks, were again 20 last week. The deaths from "fever," which had been two and four in the two preceding weeks, further declined last week to two The 142 deaths in Dublin last week included 27 of children under one year of age and 29 of persons aged upwards of 60 years, the deaths both of

* Including membranous croup.

infants and of elderly persons showed a slight decline from the number in the preceding week. Six inquest cases and three deaths from violence were registered, and 65, or nearly one-half, of the deaths occurred in public institutions The causes of 8, or nearly 6 per cent, of the deaths registered in Dublin last week were not certified.

VITAL STATISTICS OF LONDON DURING JULY, 1902.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs With regard to the notified cases of infectious diseases it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 9 4 per 1000 of the population, estimated at 4,579,107 persons in the middle of the year In the three preceding months the rates had been 10 5, 10 3 and 10 0 per 1000 respectively The rates were considerably below the average in Kensington, Chelsea, Hampstead, Stoke Newington, and Woolwich, while they showed the largest excess in St. Pancras, Finsbury, the City of London, Bethnal Green, and Southwark. The prevalence of small pox, which had been declining during the four preceding months, showed a further considerable diminution in July, among the various metropolitan boroughs this disease was proportionally most prevalent in St. Pancras Finsbury, City of London, Bethnal Green, Stepney, Battersea, and Greenwich The Metropolitan Asylums hospitals contained 305 small pox patients at the end of last month, against 1442, 1274, and 837 at the end of the three preceding months, the weekly admissions averaged 45, against 319, 260, and 145 in the three preceding months. The prevalence of scarlet fever during the month under notice showed a slight excess over that recorded in the preceding month, the greatest proportional prevalence of this disease occurred in St. Pancras, Holborn, Southwark, Lambeth, Deptford, and Greenwich. The number of scarlet fever patients under treatment in the Metropolitan Asylums hospitals, which had been 2176, 2222, and 2439 at the end of the three preceding months, had further risen to 2515 at the end of July, the weekly admissions averaged 322, against 258 274, and 251 in the three preceding months Diphtheria showed a slightly increased prevalence during July as compared with that recorded in recent months, among the various metropolitan boroughs this disease was proportionally most prevalent in St Pancras, Finsbury, the City of London, Southwark, and Lewisham. There were 1008 diphtheria patients under treatment in the Metropolitan Asylums hospitals at the end of last month, against 1035, 960, and 975 at the end of the three preceding months, the weekly admissions averaged 165, against 140, 146, and 152 in the three preceding months The prevalence of enteric fever last month showed a marked excess over that recorded in any of the previous months of this year, the greatest proportional prevalence of this disease occurred in St. Marylebone, Finsbury, Bethnal Green, Poplar, and Southwark The number of enteric fever patients in the Metropolitan Asylums hospitals, which had been 115, 127, and 195 at the end of the three preceding months, had further risen to 289 at the end of July, the weekly admissions averaged 49, against 17, 19, and 38 in the three preceding months Erysipelas was proportionally most prevalent in Hackney, Bethnal Green Stepney, Bermondsey, and Deptford. The 25 cases of puerperal fever notified during the month included three in Kensington three in Chelsea, and two each in Paddington, St Marylebone, Hampstead, Hackney, Finsbury, and Shoreditch.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various metropolitan boroughs, the deaths occurring in public institutions having been distributed among the various boroughs in which the deceased persons had previously resided. During the five weeks ending August 2nd the deaths of 6039 persons belonging to London were registered, equal to an annual rate of 13 8 per 1000, against 16 8, 15 9, and 13 9 in the three preceding months The lowest death-rates last month in the various metropolitan boroughs were 7 8 in Hampstead, 8 9 in Greenwich, 9 6 in Paddington, 9 7 in Stoke Newington 10 6 in Wandsworth and 10 9 in Lewisham, the highest rates were 16 6 in Holborn, 17 5 in Stepney and in Bermondsey, 19 4 in Southwark 20 0 in Finsbury, and 21 6 in the City of London. The 6039 deaths from all causes included 881 which were
to the principal infectious diseases, of these 52
from small pox, 177 from measles, 49 from scarle
110 from diphtheria, 203 from whooping cough,
enteric fever, and 222 from diarrhœa. The lowes

Station Hospital, Devonport, from Lieutenant Col
Coutts, who proceeds to Salisbury Plain as staff o
Surgeon General G J H Evatt, P M O, Secon
Corps Lieutenant-Colonel H Charlesworth, C
appointed to succeed Surgeon General W G Don
depôt of the London Recruiting District, and Lie
Colonel J Latchford (retired) is appointed medica
in the Dublin Recruiting District.

IMPERIAL YEOMANRY

The undermentioned officer resigns his commiss
receives a new commission subject to the provision
Militia and Yeomanry Act, 1901, retaining his prese
and seniority, viz. —

Staffordshire (Queen's Own Royal Regiment) S
Captain E W Welchman.

VOLUNTEER CORPS

Royal Garrison Artillery (Volunteers) 4th D
Henry William Martyn Strover to be Surgeon Lie
1st West Riding of Yorkshire Surgeon Captain S
to be Surgeon-Major

Royal Engineers (Volunteers) 2nd West Riding o
shire (Leeds) Joseph Holmes to be Surgeon Lieuten

Submarine Miners The Severn Division Surgeon-Captain A. Rees to be Surgeon Major.

Rifle 2nd Volunteer Battalion the King's (Liverpool Regiment) Surgeon Captain N F Roberts to be Surgeon-Major. 4th Volunteer Battalion the Devonshire Regiment Surgeon Captain F B Manning resigns his commission. 1st Volunteer Battalion the Essex Regiment Surgeon Captain St. C B Shadwell to be Surgeon Major 14th Middlesex (Inns of Court) Surgeon Captain H. M Ramsay to be Surgeon Major Surgeon Lieutenant F C. Wallis to be Surgeon Captain.

Royal Army Medical Corps (Volunteers)

The London Companies Captain H. D Buss resigns his commission

Volunteer Infantry, Brigade Bearer Company

South Yorkshire Surgeon Captain W K. Clayton from 1st Volunteer Battalion the King's Own (Yorkshire Light Infantry) to be Surgeon Captain and to command under paragraph 55A Volunteer Regulations.

Surgeon Lieutenant F J Sadler from the 2nd Volunteer Battalion the York and Lancaster Regiment, to be Surgeon Lieutenant.

Volunteer Officers' Decoration

The Volunteer Officers Decoration has been conferred upon Lieutenant-Colonel Francis Lawrance Stephenson of the Woolwich Companies, Royal Army Medical Corps (Volunteers).

Outspoken Criticism

The *Archives de Médecine Navale* an official journal published by order of the Minister of Marine," contains in its June issue a short article in which Dr. Astius Castellan who is a naval medical officer of the first class finds fault very unreservedly with the convalescent depôt for French colonial troops which has been established on the island of Porquerolles. This sanatorium, says the outspoken critic having been in existence since January 1898, ought by this time to be organised on a solid basis, but such is far from being the case. In the first place the site that has been pitched on is entirely unsuitable for the purpose. In this marvellous island continues Dr Castellan there are several places where the depôt could have been established under far better conditions, amidst the health bestowing emanations from the pine groves but instead of that it stands quite close to the village, on a bare hillock destitute of verdure and entirely unshaded. The rooms, professing to accommodate 16 convalescent men in each, are overcrowded he kitchen is only a kitchen in name being filthy full of cobwebs and shockingly furnished the latrine unprovided with water supply and very imperfectly cleansed, is placed to windward of the cantonment there are no drains pro erly so-called, only a few shallow trenches where putrescible matter lies stagnant and rotting in the sun the pharmacy and dressing room is so small and dark that it is impossible to examine or dress a patient in it finally in the immediate neighbourhood there is a village of some 250 inhabitants in which there are no fewer than seven liquor shops some of them being suspected of harbouring improper characters.

The Overcrowded Transports.

It is not easy to exaggerate the grave importance of the allegations that have been made regarding the disgraceful state of the transports conveying the colonial troops from South Africa to their various destinations. The affair has very naturally and properly given rise to a good deal of feeling in the colonies. A Royal Commission has been appointed and if the charges that have been advanced are substantiated we can only trust that the blame will be brought home to those concerned

The Welsh Hospital.

A handsome brass tablet to the memory of six members of the staff of the Welsh Hospital who died during the recent war in South Africa was unveiled in St. David Cathedral on August 14th by Lord Penrhyn The names on the tablet are those of Professor A W Hughes Professor T Jones Dr H. Davies T R Eames (dresser) Marion Lloyd (matron and Florence L. Sago (nursing sister).

ROYAL COLLEGE OF PHYSICIANS OF LONDON.—In the list of gentlemen admitted on July 31st as Members of the College published in THE LANCET of August 9th p. 396 the following name was accidentally omitted —Andrew Elliot M A. M.D Edin.

THE DUTIES OF A MEDICAL MAN AND THE LAW OF LIBEL

To the Editors of THE LANCET

SIRS,—I have read with interest the letter of Dr Shaw Mackenzie on the above but must confess that I think he has taken too gloomy a view in respect of the dangers run by medical men in the particular instance he quotes. He states in his letter that publication of a wife's disease to the husband would undoubtedly be sufficient to cause an action to lie against the medical attendant and suggests that an alteration in the law of libel is desirable. It is quite clear from the recorded cases that such a statement made *bonâ fide* by a medical man would be held to be privileged." Only lately in a case held at Leeds Assizes the learned judge extended the privilege in this respect not only to the communication made to the husband but also to the employer and also to the housekeeper in whose employment and under whose domestic care the wife was. Further than this privilege can hardly be expected to extend

I am Sirs yours faithfully

A. GEORGE BATEMAN

August 18th, 1902. General Secretary Medical Defence Union

PATENT FOODS

To the Editors of THE LANCET

SIRS,—I have read with much interest the valuable and exhaustive address by Dr R. Hutchison on Patent Foods published in THE LANCET of July 5th (p. 1) There is one point, however in respect of somatose that is worthy of note Dr Hutchison after stating that somatose is a good albumose food and a very rich one, containing 80 per cent. of digested proteid goes on to say that if it is given in anything like large quantities it is apt to produce diarrhœa and for that reason its use is seriously restricted in practice"

I do not think that this is a universal experience. I have used somatose more or less since 1897 and I have scarcely ever found that it has produced any diarrhœa and I am anxious to say a good word for it. I think that it is more than probable that the mode of administration has a great deal to do with the results obtained. It is imperative, in the exhibition of somatose, that it should be administered at first in small doses but frequently three, four or more times in 24 hours, gradually increasing every few days until the full dose is obtained. Another thing is also essential—that is, that it should be in *complete* solution before being swallowed. The only cases in which I have seen slight diarrhœa in the use of somatose are those in which this precaution has been neglected and the substance has been lumpy I have given somatose in adults in quantities of from three to six drachms per day and to children from 45 to 90 grains without any unpleasant effects and with the best results.

In July, 1899 I wrote a small brochure on somatose which appeared in the *Scalpel* during that month On reference to it I find that I have made no mention of diarrhœa but as there stated it has done me yeoman's service the great increase of body weight being astonishing as much as from two to three pounds having been put on in seven days. Dr J L. Landau in *Die Heilkunde* September 1898 quotes a series of cases in which he exhibited somatose and he states The manner of preparing this solution is deserving of very special consideration. Into a wineglass containing a tablespoonful of water or other medium the desired quantity of somatose is poured and the resulting paste stirred for a few minutes until a *complete solution* is obtained" He further states that when given to children in the following manner—one gramme for the first three days and then increased up to three grammes in eight days—no diarrhœa has occurred He has also used it in gastro-intestinal cases where there was total loss of appetite, diarrhœa, and vomiting from one to five grammes of somatose being given at first gradually increased to eight grammes As a result by the second day the stool had decreased and by the eighth the diarrhœa had altogether ceased

The experience of many other continental physicians coincides with that of Dr Landau, indeed, he quotes them frequently in support of his own statements as to the value of somatose, and there can be no doubt that this preparation has been administered in sufficient quantities to produce highly beneficial results, May we not, therefore, be justified in assuming that in those cases in which the results have been unsatisfactory the method of administration of somatose has had more to do with the production of diarrhœa than has the preparation itself, seeing that when certain precautions are taken diarrhœa is mostly absent and that its use has been attended with marked success in the hands of very many physicians?

I am, Sirs, yours faithfully,
T POYNTZ WRIGHT,
St. Neots Hunts August 18th Medical Officer of Health

THE SIMULATION OF ABDOMINAL DISEASE BY INTRA-THORACIC LESIONS

To the Editors of THE LANCET

SIRS,—In a leading article in THE LANCET of August 16th you refer to papers bearing on the above subject by Mr H. L. Barnard[1] and by Dr Jane H. Walker in the Mirror of Hospital Practice,[2] and you well emphasise the necessity of being on one's guard and making examination of the thoracic region, especially in the case of surgeons Now, in most of these cases, if not in all, careful examination of the chest will, even at the earliest period, throw light on the problem Mr Barnard candidly admits that error in the diagnosis is usually due to neglect on the surgeon's part to have the chest examined—"the diagnosis is nearly always easy, if suspicion is aroused and the surgeon is aware of this deceptive condition" With regard to the case reported by Dr Jane Walker, it is, to say the least, unsatisfactory It is stated that at a period when the respiration varied from 18 to 54 per minute and the pulse-rate from 90 to 128 "her chest, which was carefully examined every day, showed no abnormal signs" Now, Sirs, it would be interesting to know exactly in what the examination of the chest consisted For my part, I cannot believe that diaphragmatic or other obscure basal pleurisy could possibly exist without a marked diminution, if not abolition, of the shadow movement (Litten's) on the corresponding side On the other hand, if the lesion was really under the diaphragm the shadow might remain unaffected. The abolition or restriction of the shadow movement would be quite compatible with negative signs on auscultation and percussion There is another expression in the narration of this case which deserves notice—viz "Some muco-purulent material being expectorated which was examined for both tubercle bacilli and other organisms with a negative result." What is meant by 'other organisms"? Are we to believe that the sputum in this particular case was sterile? Was the sputum injected into animals?

May I end by saying that it would be well if in narrating important cases authors would state the precise details of their methods of examination It is easy to conceive that the omission of a single diagnostic test might convert a comparatively plain situation into one of grave difficulty

I am, Sirs, yours faithfully,
Henrietta street W August 18th, 1902. A. G AULD

THE ETHICAL SECTION AT THE RECENT MEETING OF THE BRITISH MEDICAL ASSOCIATION

To the Editors of THE LANCET

SIRS,—While reporting the transactions in the Section of Ethics (annual meeting British Medical Association) as stated in THE LANCET of August 9th, p 390, your representative, as a rule extremely accurate and impartial, has on this occasion, unwittingly I am certain, fallen into two errors relative to myself The first, a very minor slip on p 390, second column, third line from the top "more than £1000" should read "*nearly* £1000" The second, rather more important, p 391, is contained in the concluding paragraph, "The *motion* was carried with one dissentient vote, given by Dr W Muir Smith of Eastbourne." As a matter of fact, I did not vote either way, at least, I have no recollection of voting in favour of, and am absolutely certain I did not vote against, the resolution Certainly there was one dissentient, and the confounding myself with another may be explained by the fact that the voter in question was seated next to me. I am, Sirs, yours faithfully,
Eastbourne August 13th, 1902. WM MUIR SMITH.

WALES AND WESTERN COUNTIES NOTES

(FROM OUR OWN CORRESPONDENTS)

Memorial Tablet to the Staff of the Welsh Hospital

THERE was unveiled on August 14th in St. David's Cathedral, by Lord Penrhyn, a memorial tablet recording the names of the members of the medical and nursing staff of the Welsh Hospital who died during the war in South Africa The inscription on the tablet was —

THE WELSH HOSPITAL
IN SOUTH AFRICA.
This Tablet was placed in
this Cathedral Church by the
Committee of the Welsh Hospital
in South Africa in Memory of
those members of the medical and
nursing staff of the hospital
who died for their country
in the Boer war in the years
1900 and 1901
Professor ALFRED WILLIAM HUGHES, M.B F R C S
Professor THOMAS JONES M.B F R C S
HERBERT DAVIES M B
THOMAS RICHARD EAMES dresser
MARION LLOYD Royal Red Cross Matron
FLORENCE LOUISE SAGE, nursing sister
Gorphwysant

The graceful eulogy of Lord Penrhyn when he handed over the memorial to the care of the Dean and Chapter and the impressive tribute of Dean Howell in accepting the charge will long be remembered by those who took part in the cathedral service. In the course of his address the Dean said that not less brave or less chivalrous than those who were stricken down by disease or the sword were those who day by day and night after night stood face to face with death within the Welsh Hospital, for with them was not the rush and excitement of the battlefield, nor the wild impulse of the fray, nor the overmastering passion for victory, but only the calm consciousness that they were doing their duty to their country and countrymen. It will be remembered that the Welsh Hospital was established in the spring of 1900 and that Professor Alfred Hughes, after acting as organising secretary in this country, went out to South Africa as chief surgeon upon the death of Professor Thomas Jones The hospital was first of all located at Bloemfontein, afterwards at Springfontein, and was finally converted into an officers' hospital at Pretoria. A total sum of about £12,000 was subscribed in support of the undertaking and of this £8000 were expended Of the balance £1200 have been given to hospitals in Wales and the remaining £2800 are to be distributed among incapacitated Welsh soldiers and the widows and orphans of those who died during the war

Small pox

During the week ending August 16th one case of small-pox occurred at Caerphilly and terminated fatally There is no means of isolating cases of infectious disease in this district, but an iron hospital has been hastily erected There were three cases of the disease reported in Neath, two of the patients being officers of the workhouse The epidemic appears practically to have subsided in Swansea, one case only having been reported during the period named, while in the previous week there were eight cases. The vaccination stations in Swansea were closed on August 14th

Maintenance of Lunatics in Workhouses

The Bristol board of guardians has decided to ask the Local Government Board to promote legislation for the purpose of securing to boards of guardians a grant of 3*s* per week towards the maintenance of lunatics, imbeciles, and epileptics who are not sent to lunatic asylums or licensed houses but who are kept in workhouses or in special institutions connected with workhouses. At present boards of guardians receive from the exchequer grants of the county council 4*s* per week towards the maintenance of each pauper lunatic in a lunatic asylum or licensed house, and the suggestion of the Bristol board embodies a recommendation of the Royal Commission on Local Taxation contained in its report dated May 28th 1901.

[1] THE LANCET August 2nd, 1902 p 280
[2] THE LANCET August 16th, 1902, p 440.

Incorporated Society of Medical Officers of Health

Dr Richard Prichard medical officer of health of Llandaff and Dinas Powis has been elected President of the West of England and South Wales branch of the Incorporated Society of Medical Officers of Health.

Diphtheria at Bristol

In his recently issued annual report on the health of Bristol Dr D S. Davies deals with the question of the medical inspection of children attending public elementary schools, and after detailing certain information obtained from other large towns he states that no systematic supervision over school-children in order to detect early or unrecognised communicable disease appears ever to have been attempted in England. The prevalence of diphtheria among school-children in Bristol during 1900 and 1901 compelled Dr. Davies to take very definite steps to stamp out the disease and he was apparently successful in his endeavours The course which he adopted was to examine the classmates of those children who were reported to him as having developed clinical diphtheria The labour involved in this procedure may be judged from the fact that during 1901 no fewer than 2527 bacteriological examinations were made by the medical officer of health or by his deputy Mr J O Heaven. Having found that in a large percentage of these contacts there were either in the throat or nose typical diphtheria bacilli or the so-called pseudo bacilli Dr Davies was met with the administrative difficulty that in the absence of marked constitutional symptoms the patients could not be admitted into the hospital even if there had been room for the large number affected while it was probable that any treatment at home would only be imperfectly carried out. In the case of the Avonmouth outbreak it was therefore arranged for these suspected carrier" cases to attend daily at the hospital as out-patients, when antiseptic washes were applied by the nurses under medical direction. Periodical bacteriological examinations were made to determine re-admission to school and the outbreak was extinguished by the end of the year

Vaccination Expenditure

At the meeting of the St. Thomas (Exeter) board of guardians held on August 15th the report of the committee appointed to consider the question of vaccination fees was presented The committee recommended that the Local Government Board should be asked to approve of the insertion of a clause in the public vaccinators contracts to the effect that when more than one person is vaccinated at a time in an asylum hospital, or other public institution the fee shall be 2*s* 6*d* for each case if the institution is situated in the parish in which the public vaccinator is resident, and 4*s* if situated outside such parish. The report further stated that the committee was of opinion that the public vaccinator for the Exmouth district should receive 28 days notice to terminate his contract, and in conclusion the suggestion was made that the permission of the Local Government Board should be obtained for sanction to pay £18 expended by the public vaccinators in the purchase of calf lymph for revaccination. The guardians resolved to adopt the report.

Coronation Gifts by a Medical Man.

During the course of the coronation festivities at Sidmouth Devon, on August 9th Dr T H Stocker Pullin presented mugs suitably inscribed to about 1000 school-children. Dr Pullin two and a half years ago completed 50 years of medical practice at Sidmouth.

August 18th.

SCOTLAND

(FROM OUR OWN CORRESPONDENTS)

Glasgow University

THE King has been pleased, on the recommendation of the Secretary for Scotland to approve of the appointment of Mr J Graham Kerr M.A. Christ's College Cambridge to the Professorship of Natural History in the University of Glasgow vacant by the resignation of Professor John Young It is understood that for the present the chair is to include geology as well as zoology but the appointment has been made subject to the power of the University Court to separate the two subjects and to appoint either a lecturer or professor of geology In the recent grant from the Carnegie Trust a sum of £7500 was marked off for this purpose. Professor Young who now withdraws from active work, has been one of the most conspicuous figures of the medical quadrangle for many years He will take with him in his retirement the good wishes of many generations of Glasgow students.

Ether drinking in Glasgow

The chief constable of Glasgow in a special report to the magistrates committee states as a result of a recent series of inquiries that he is convinced that a considerable quantity of ether is purchased from some few chemists for drinking purposes, that the practice is limited to certain low-class localities and that the number of ether-drinkers is relatively small. As a result of this report the Parliamentary Bills Committee has been instructed to take the necessary steps to secure the inclusion of ether in the list of poisons' scheduled under the Pharmacy Act. This can only be done by the authority of the Privy Council.

The Treatment of Inebriates

An experiment in the treatment of habitual drunkards instituted by the corporation of Glasgow has now been in progress for some 18 months and a few days ago an official visit of inspection was paid by the town council to the institution in which it is being conducted. This is known as the Girgenti Home and is situated about half an hour's railway journey from the city It is built on an estate extending to about 55 acres which was purchased for the purpose by the corporation. The qualifications for admission to the home are a certificate as a habitual drunkard and the fact of conviction for drunkenness four times within 12 months. The inmates are made to engage in dairy and laundry work and in gardening and other outdoor occupations, and the products of their work are sold with the result that the working expenses for the first year have been fully met. Up to the present date 61 patients all women have been admitted. The period of residence is limited to three years, but when deemed advisable a patient may be allowed to leave on licence, and this has been possible in several instances with satisfactory results In an address delivered on the occasion of the official inspection Mr J Carswell, L.R.C.P. Edin. the chairman of the inebriates committee, claimed that the results were so far full of encouragement, more especially in view of the fact that at present they were dealing with habitual drunkards of many years standing He anticipated an even more satisfactory report when they were able to send to the institution those less habituated to vicious habits At the conclusion of the inspection an address to the inmates was given by the Lord Provost.

Aberdeen University

Dr W F Croll has been appointed to hold for one year the Phillips Scholarship in connexion with the Aberdeen University

The Caledonian Medical Society

The annual meeting of the Caledonian Medical Society was held in Inverness on August 5th. In the afternoon the members visited the Northern Counties District Asylum at the invitation of Dr J Keay who entertained them at lunch. Dr Ogilvie Grant (Inverness) president of the society occupied the chair and after lunch the annual business meeting was held The secretary reported that 25 new members had joined since the last meeting and there were 200 names on the roll There were 115 members resident in England and foreign countries and 85 in Scotland Dr H Cameron Gillies (London) was unanimously elected president and Dr George Mackay (Edinburgh) vice-president Dr Grant delivered an excellent retiring address The members dined together in the Royal Hotel. The toast of Prosperity to the Society" was proposed by the Rev Dr Norman Macleod in happy terms, and the new president (Dr Cameron Gillies) gave the standing toast of Caledonia," and Mr James Barron (Inverness) and Dr W Bruce (Dingwall) were called upon to respond. The meeting was pleasant and successful.

August 19th.

IRELAND

(FROM OUR OWN CORRESPONDENT)

Overcrowding of Monaghan and Cavan District Asylum

IT would appear from the report of Dr E M Courtenay, inspector of lunatics, that at his last inspection of this asylum (June 12th and 13th) there were 838 patients, an increase of 27 from the previous inspection. In last year's report attention had been drawn to the very serious overcrowding which then existed, and no steps have been taken to remedy this congested state of the asylum, nor had any plan been decided on by which additional accommodation could be provided There were now 115 patients in excess of the capacity of the institution The bedrooms had to be converted into dormitories, the chapel dormitory, which was occupied by the women, had to be taken from them and given to the men in order to meet the increasing numbers on the male side, and the dining hall, kitchen, and stores were insufficient for the wants of the present asylum population. Such overcrowding called for immediate attention and for immediate steps being taken to lessen it. The inspectors threaten to bring under the Lord Lieutenant's notice the condition of the asylum and to point out that the provisions of the Local Government Act have not been complied with. It would then be for his Excellency to decide whether, in the circumstances, the Government grant could be paid. Notice has been given that steps be taken to erect additional wings so as to supply the necessary accommodation. Another solution would be to build a new asylum for Cavan

Belfast District Lunatic Asylum

Dr W Graham, medical superintendent of the Belfast Asylum, has just issued his report for the year ended Dec 21st, 1901 The total number of patients under treatment was 1108 (552 males and 556 females) There were 273 admissions during the year and 107 discharges The recovery rate was 25 3 per cent., as compared with 21 4 per cent. in the previous year The deaths were 71 in number (44 males and 27 females) Eight deaths were due to phthisis and none from either accident or suicide The gross expenditure for the financial year ending March 31st, 1902, was £22,460 6*s* 7*d*, being a capitation cost of £23 1*s* 4*d* or a diminution of £1 12*s* 1*d* per head on the preceding year The most notable event of the year was the purchase of a farm abutting on the asylum grounds of 88 acres The land is of good quality and by situation and accessibility admirably adopted for the purposes required There is also a memorandum of inspection, by Sir George P O'Farrell, on Nov 20th, 1901, in which, he says, he was pleased to find every part of the asylum clean and orderly and that the general management of the institution bears distinct evidence of the zeal and ability of the medical superintendent in the discharge of his duties

County Antrim Infirmary

At the monthly meeting of the board of management of this institution, held on August 15th, a long discussion took place in reference to the greatly increased expenditure on the house, due to the fact that there is an unusually large number of patients at present, almost every bed being filled It was reported that there was a great increase in the number of patients from outlying parts of co Antrim The feeling of the board of management was that great care should be taken to investigate thoroughly whether the patients were able to contribute to their maintenance while in the institution.

Londonderry Asylum

The Londonderry board of guardians and the committee of management of the Londonderry Asylum are at cross purposes in reference to the admission of patients It seems that at present there are 100 patients in excess of the legitimate accommodation and as a result the committee of management of the asylum wrote to one of the boards of guardians in the county of Londonderry requesting it to direct its medical officers not to send lunatics to the asylum unless where absolutely compelled to do so until some accommodation was provided. About the same time, however, circulars were received from the Local Government Board directing boards of guardians to instruct their medical officers gradually to send all imbeciles in the workhouses to the asylums, which were the proper places for their treatment This suggestion of the Local Government Board was followed out by some of the boards of guardians, with the result that when lunatics were sent to the Londonderry Asylum the committee of management ordered that they should be sent back to the workhouses again The matter came to a crisis when on August 16th, at a meeting of the Londonderry board of guardians, a letter was read from the resident medical superintendent of the asylum to the effect that the committee of management had decided that owing to the excessive overcrowding of that institution it could not admit two of three patients sent from the workhouse to the asylum, but as the other was an acute one she would be admitted It was urged that, except in extremely serious cases, application for the admission of insane inmates of the workhouse to the asylum should not be made at present. The clerk of the workhouse then brought before the guardians a report of the inspection of the insane inmates there, made by Sir Plunkett O'Farrell, inspector of lunatics, who said that there were a few who certainly required more skilled attention than that afforded by the workhouse. Skilled nursing was, it was reported, absolutely necessary in the case of many old and demented patients, and it was a mistake to say that such insane patients, because they were not dangerous should be treated in a workhouse instead of a lunatic asylum The master of the workhouse pointed out that some of these patients referred to by the inspector had been sent to the asylum, which the committee of management had referred to in the letter of the medical superintendent After discussion, in which the medical officer of the workhouse stated that he would not accept the responsibility of the care of lunatics in the workhouse whom he considered should be treated in the asylum, it was finally decided to send lunatics certified by the medical officer as acute cases to the asylum for admission, and if they were refused admission the responsibility would attach to the committee of management.

The Malversation of Funds at the Faculty of Medicine

THE *juge d'instruction* has just given a judgment with regard to the malversation of funds at the Faculty of Medicine which led to the arrest of the cashier, M Imoville, and also of the secretary of the Faculty, Dr Pupin, who was responsible for the treasury [1] M Imoville had drawn upon the funds which were confided to his care to the amount of some 76,000 francs, with a view to helping some of his friends who had fallen upon evil days He drew with such liberality that he practically emptied the treasury Dr Pupin, who in great part has indemnified the professors whose salaries were in abeyance owing to the action of the cashier, has been released, it being considered that there was no case to go to a higher court (*ordonnance de non lieu*) With regard to M Imoville, who has just been tried by the Correctional Tribunal on a charge of abuse of confidence, Dr Motet had been charged with the duty of examining him with regard to his mental condition and his report was that Imoville was not altogether responsible None the less, he has been condemned to 13 months' imprisonment with right of appeal and to a fine of 25 francs

The Action of Gelatin on the Plasticity of the Blood

M Lancereaux recently laid before the Academy of Medicine some researches of M Marc Laffond and M. André Lombard which tend to show that gelatin acts very vigorously as a modifier of the plasticity of the blood. This has already been proved by means of hypodermic injections and local applications in the treatment of hæmorrhages and of aneurysm, but the idea of attributing the phenomena of glycosuria, of albuminuria, and of hæmophilia, to a primary degeneration of the blood and with a certain modification of its cryoscopic properties, even if it have already been formulated, has never caused this series of symptoms to be regarded as a continuous pathogenic entity, although these symptoms are of frequent occurrence in certain morbid states This is what constitutes the original part of the treatment described by M Laffond and M.

---

[1] THE LANCET, June 21st

Lombard—viz. that gelatin will act in the same manner even if given by the mouth 15 grammes divided into four doses produces a remarkable effect in hæmophilia. In albuminuria and diabetes this method of treatment appears to be very efficacious in so far that it removes the symptoms of the disease. The method of treatment can be continued for a long time and all the more readily in that giving gelatin as part of the ordinary diet is absolutely harmless.

Apollinaris and the Academy of Medicine

The Mineral Waters Committee of the Academy of Medicine, whose duty it is to advise the Minister concerned as to giving permits for the advertising and sale of mineral waters in France, has recently come to an important decision. It has decided to withdraw from the Apollinaris Company the right of selling its water in France, a right which it has enjoyed since 1868. To explain this fact it must be remembered that of late years applications for the permission to sell mineral waters have increased to an enormous extent, and the Academy accordingly some little time ago decided not to give any new permits for the sale of mineral waters except in the case where a water presented some particular novelty of composition. Stringent regulations were drawn up with a view of safeguarding the purity of the springs and of preventing pollution of the water during bottling The result is that it has become exceedingly difficult to get a mineral water accepted by the Academy and when all the French mineral water firms were bound down by these regulations it became necessary to apply them also to foreign mineral waters for it could not be expected that the Academy of Medicine should show itself more indulgent to foreign mineral waters than to French waters. So it follows that a number of so-called Hungarian purgative mineral waters artificially prepared, have had the permission of the Academy of Medicine for sale in France withdrawn despite diplomatic representations which have been made. So also, the permission to sell which the Apollinaris Company has enjoyed since 1868 was withdrawn in April by the Academy of Medicine, the reason being given that the composition of the water as sold varied in a great degree, that it was probably not identical in all respects with the natural spring water and that not sufficient precautions were taken with regard to its collection and bottling The Apollinaris Company has therefore addressed to the Minister concerned a protest containing answers to the critics of the Academy and this latter body made a fresh examination into the question and Professor Landouzy President of the Mineral Waters Committee, issued a report definitely deciding to withdraw the permission of the Academy for the sale of Apollinaris Water

Sleep and Anæsthesia produced by Electric Currents.

At the meeting of the Academy of Sciences held on July 21st M. Leduc informed his hearers that it was possible by means of electric currents to bring about almost instantaneously complete inhibition of the cerebral centres in the following manner A source of continuous current is taken and in the circuit is placed an interrupter capable of giving some 200 interruptions per second together with a milliampère meter The animal to be experimented upon has its head and back shaved the kathode electrode, wetted with salt water is placed on the head and the anode on the back. With the interrupter working the force of the current is gradually increased by bringing more and more cells into play until slight general muscular contractions are noted. The animal then falls over and its respiration stops. The current is then lessened until respiration begins again The animal then falls into a sleep respiration and circulation go on quietly but it is quite insensible to pain, only a few reflex movements being observed Dogs have been kept in this condition for two hours. Directly the current stops they wake up and appear quite happy and lively The current must be pushed rapidly up to the contraction stage if given very gradually it is painful. M Leduc found the best results to occur with a pressure of from 12 to 30 volts, with from 150 to 200 interruptions per second and with a current of from two to 10 milliampères, according to the size of the animal. Local anæsthesia can be obtained in man by placing the kathode over a nerve, the median in the wrist for example. A pricking sensation is felt which is not painful and the field supplied by the nerve becomes quite insensitive.

BERLIN

(FROM OUR OWN CORRESPONDENT.)

Tuberculosis Bovine and Human.

PROFESSOR MAX WOLFF chief physician to the Berlin University clinic for pulmonary diseases has made a very interesting experiment tending to prove that bovine tuberculosis (Perlsucht) and human tuberculosis are identical. Full details of the investigation are given in the *Deutsche Medicinische Wochenschrift* of August 7th. It will be remembered that in the remarkable address which Professor Koch delivered at the British Congress on Tuberculosis held in London in July 1901 he expressed the opinion that tuberculosis was very seldom communicated to the consumers of the milk of tuberculous cows and in support of this view he drew attention to the rarity of primary tuberculosis of the intestine in the human subject Inoculation of an animal is necessary for the purpose of showing whether a given case of tuberculous disease of the intestine is to be regarded as ordinary human tuberculosis or as perlsucht, according to Professor Koch human tuberculosis is not communicable to the lower animals. Professor Wolff had under his care a man suffering from primary tuberculosis of the intestine at the necropsy it was ascertained that the lungs were healthy the tuberculous infection being confined to the intestines the spleen and the peritoneum. Guinea pigs were inoculated with portions of the tuberculous spleen and on the animals being killed from seven to eight weeks afterwards they were found to show general tuberculosis of the lungs, liver and spleen the presence of tubercle bacilli being demonstrated by the usual methods. A calf five months old which had been already tested with tuberculin and found to give no reaction was immediately inoculated with tuberculous material from the guinea pigs. An emulsion made with portions of the lungs and spleen of the guinea pigs was injected into the calf's neck the result being that a large growth developed at the place of the injection and the adjacent glands became swollen. A month after the inoculation the calf was tested with tuberculin and gave a positive reaction after the lapse of a further period of seven weeks the test was repeated and again the reaction was positive. The animal was killed 83 days after the inoculation with the material obtained from the guinea pigs and at the necropsy all the symptoms of perlsucht were found. At the place of the injection there was a large growth containing caseous masses, similar formations being present in the glands in the neighbourhood the pleura was covered with numerous tumours of varying size there were also growths on the pericardium and the liver and tuberculous deposits in the lungs and kidneys Bacteriological examination demonstrated the presence of tubercle bacilli, the virulence of which was proved by inoculation of guinea pigs. As the inoculation of the calf with tuberculous material was quite successful it follows from these observations that the tuberculous deposit in the man's intestine when viewed in the light of Professor Koch's opinions must be regarded as perlsucht.

Statistics of the Medical Profession in Europe

A very interesting article embodying various statistics relative to the medical profession throughout Europe has been published by Dr Prinzing of Ulm in the *Zeitschrift für Socialwissenschaft* a journal devoted mainly to questions of political economy In Germany the total number of medical men and the proportion per 10 000 inhabitants in several specified years were as follows 13,728 (or 3 2 per 10 000) in 1876 16,824 (or 3 3 per 10,000) in 1887 24 725 (or 4 4 per 10 000) in 1893 and 27 374 (or 5 1 per 10 000) in 1900 It will therefore be seen that up to 1887 the numerical increase of the medical men only kept pace with the numerical increase of the general population but that since 1893, and especially in 1900 the former gained in numbers far more rapidly than the latter In 1898 a special investigation was made for the purpose of ascertaining how many medical men possessed of legal qualifications practised as homœopaths the result being that only 240 acknowledged themselves to be such It was remarkable that in Würtemberg 3 7 per cent of the medical men professed homœopathy the proportion in the other states varying from 0 6 to 0 9 per cent. An enumeration of the unqualified practitioners was also made in 1899 and it was found that for each 100,000 of the population they numbered 16 4 in Saxony, 5 3 in Prussia, and 1 3 in Alsace Lorraine The distribution of the medical profession according to area, or density as it might be called, was found to vary greatly in different parts of Germany In Hesse, for instance, there was one medical man for each 28 square kilometres (10 8 square miles), while in East Prussia there was one medical man for each 192 square kilometres (74 square miles) With regard to the distribution of the medical profession in the towns the article states that in towns of more than 100,000 inhabitants there was an average of 10 8 medical men per 10,000, in towns of more than 40,000 inhabitants there were 9 2 medical men per 10,000, in towns of more than 20,000 inhabitants there were 7 6 medical men per 10,000, in towns of more than 5000 inhabitants the ratio was 6 0 medical men per 10 000, whilst in towns of fewer than 5000 inhabitants the ratio was only 2 4 medical men per 10,000 The number of the medical men, of course, varied considerably according to the character of the population, for they were relatively few in towns where the bulk of the people were of the working class. For example, at Linden in Hanover, where 79 6 of the population were employed in factories, there were only 3 1 medical men per 10,000, whilst in Königsberg, where only 35 4 per cent. were factory workers, and in Dresden, where 48 1 per cent. were factory workers, the proportion of medical men per 10,000 was 10 5 and 9 1 respectively Dr Prinzing then gives figures relative to the Austro-Hungarian monarchy In Austria there were 9494 medical men, of whom no less than 5819—i e., 61 per cent — hold fixed appointments, for the Austrian law requires local authorities to provide medical aid in places where there would otherwise be no medical man. The proportion of the medical profession to the general population has not of late varied so remarkably as in Germany The following ratios of medical men per 10,000 of the total population have been recorded 3 8 in 1848 3 6 in 1858, 2 4 in 1868, 3 5 in 1876, 3 1 in 1886, and 3 6 in 1896 The corresponding ratios in Vienna were 17 0 in 1874 and 13 0 in 1896, the decrease being only an apparent one, due to the fact that the area of the metropolis has been recently enlarged by the incorporation with it of several suburbs with relatively few medical men In Hungary in the year 1897 there were 2 8 medical men per 10,000 of the general population In the other countries of Europe the number of medical men per 10,000 of the population was as follows in Italy 6 3, in Switzerland 6 1, in France 3 9, in Spain 7 1, in Belgium 5 2, in Denmark 6 4, in Norway 5 3 in Sweden 2 7, and in Russia 2 7 In England, if the medical officers of the army, the navy, and the colonial services be included, the ratio per 10,000 of the population was said to be 5 7 in 1881, 6 0 in 1886, and 6 1 in 1895, if, however, the above specified classes be excluded the ratio falls to 4 8 In Scotland the ratio was 7 7 and in Ireland it was 5 6 In London in the year 1886 the ratio was 10 6 and in 1895 it was 12 8, in Liverpool it was 6 4, in Bristol it was 8 1, and in Sheffield it was 3 8 In several European capitals the number of medical men per 10,000 of the population was as follows in Berlin 14 1, in Vienna 13·0, in Budapest 16 4, in Paris 9 7, in Brussels 14 7, in London 12 8, in Madrid 24 6, in Christiania 12 1, in Stockholm 7 7, and in Copenhagen 12 7 It must be remembered that in the above statistics the figures given for the various countries do not all belong to the same year, for the census year is not the same in each country For instance, the figures given for Italy are of the year 1885, those for France are of 1892, those for Great Britain are of 1895, and those for Germany are of 1900

CANADA.

(FROM OUR OWN CORRESPONDENT)

Lunatics in Canada

ACCORDING to a bulletin which has been recently issued by the Census Department at Ottawa there are no less than 16,495 people of unsound mind in the total population of the Dominion of Canada In addition to this there are 6174 deaf and dumb and 3279 blind This means a total of 25,948 infirm persons in the Dominion, of whom 13 929 are males and 12,019 are females 10 years ago the record was 13,365 of unsound mind, 4819 deaf and dumb, and 3368 blind Of the total number of infirm persons to-day 5269 have been so afflicted from childhood. The seemingly great increase in the insane population in the last decade may be put down to the fact that prejudices which formerly kept down the total number of the institutional insane have been to a great extent removed.

Death of Dr Wyatt Johnston of Montreal

Dr Wyatt Johnston, one of the leading physicians of Montreal and a foremost man in sanitary science in the Dominion, died at the Montreal General Hospital on the morning of June 19th from pulmonary embolism following upon an attack of phlebitis The late Dr Johnston graduated from McGill University in 1885 and ever since has been connected with the staff of his *alma mater* He spent several years in the laboratories of Virchow and Growitz and had but recently succeeded to the chair of sanitary science at McGill rendered vacant through the resignation of Dean Craik He was an original worker in the field of pathology and a frequent contributor to English and Canadian medical journals Latterly he had given much study to medico legal matters, upon which subject he was considered an authority in Canada.

Annual Meeting of the Medical Society of Nova Scotia.

The thirty fourth annual meeting of the Medical Society of Nova Scotia was held at New Glasgow, Nova Scotia, on July 2nd and 3rd, under the active presidency of Dr John W McKay of that city A paper by Dr H P Clay of Pugwash, dealing chiefly with the injustices from which the medical profession suffer, particularly at the hands of large corporations, elicited considerable discussion and a committee was appointed to report at the next meeting Amongst others who contributed papers for discussion were Dr George E. Armstrong and Dr F G Finlay of Montreal who read the addresses in surgery and medicine respectively The next meeting of the society will take place next July at Antigonish, Nova Scotia The following were the officers elected —President Dr J J Cameron, Antigonish, First Vice President Dr W G Putnam, Yarmouth, Second Vice-President Mr Murdoch Chisholm, Halifax, and secretary-treasurer Dr Huntley Macdonald, Antigonish, Nova Scotia.

Annual Meeting of the Maritime Medical Association.

The twelfth annual meeting of the Maritime Medical Association was held at Charlottetown, Prince Edward Island, on July 9th and 10th Amongst others from a distance who were present and contributed papers were Dean W B Gleikie of Trinity Medical College, Toronto, Dr H. D Hamilton of McGill University, Montreal, and Dr Stoddart of Pueblo, Colorado, U S A. The following officers were elected for the ensuing year President, Dr Murray McLaren, St John, New Brunswick, Vice President for Prince Edward Island, Dr P C Murphy, Tignish, Vice President for New Brunswick, Dr R. L Botsford, Moncton, Vice-President for Nova Scotia, Dr G M Campbell, Halifax, secretary, Dr T D Walker, St. John, New Brunswick, and treasurer, Dr O A. McPhail, Summerside, Prince Edward Island

Living 50 Feet below the Surface of the Earth

The *Canadian Journal of Medicine and Surgery* has the following interesting report of an extraordinary case of burial alive, the issue of which was surprisingly fortunate —

> On June 24th a well-digger named Joshua Sanford, owing to the collapsing of the brick casing of a well at the Scott farmhouse near Paris (Ont.) was imprisoned in the well for close on 100 hours In order to rescue Sanford a shaft 50 feet in depth was made parallel to the well in which he lay When on a level with the position occupied by the man a tunnel was constructed from the shaft to the well large enough to permit the passage of a man s body and the first nourishment that he received in nearly 80 hours was given him On Friday night June 27th it was found that his right leg was held tightly in a mass of brick, so that it could not be moved A second tunnel three feet beneath the first one was put in and cased The rescuers John Carnie William Hamilton and Richard Doyle introduced scantling through the lower tunnel so as to support the weight of the mass of collapsed brick and sand surrounding Sanford s body and then picked out the bricks so that the imprisoned leg could be released without causing the mass of débris to fall lower down Sanford s head was then lowered to the same level as his feet and he was withdrawn from the well through the lower tunnel and carried up to the surface in a bucket at 6.30 Saturday, 99½ hours after the accident had occurred After he had been placed in bed he was examined by Drs R Dunton, Burt Sinclair and Loggie of Paris Addison of St George and Stanley of Brantford They found that Sanford had suffered comparatively little during his incarceration and long period of abstinence from food There were a number of slight scalp wounds on his head caused by falling bricks There were wounds and bruises all over the body and several contusions on the right leg which anchored the man in the well and around which a rope had been fixed in an effort to drag him out of the hole This leg was apparently paralysed and this condition

was expected to exist for some time. His speech was nearly normal. His pulse was 140, his temperature 98° F, and the respirations 44.

Everything points to Sanford being a man of extraordinary pluck and endurance who owes his life to the exhibition of his manly qualities.

Toronto, August 7th.

Medical News.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—The following gentlemen having passed the necessary examinations and having conformed to the by-laws and regulations have been admitted Members of the College and have received their diplomas:—

Joseph Ebenezer Adams, St. Thomas's Hospital; Alfred Cole Ambrose, Cambridge University and Guy's Hospital; Cauldwell Hamilton Anderson, Melbourne University and St. Thomas's Hospital; Kenneth Anderson, Guy's Hospital; George James Smith Atkinson, St. Mary's Hospital; Harold William Atkinson, M.A. Camb., Cambridge University and St. Bartholomew's Hospital; Leslie Baldwin Aveling, B.A. Camb., Cambridge University and London Hospital; Charles Harrison Barber, B.A. Oxon., Oxford University and King's College Hospital; Edward Augustus Bell, King's College Hospital; Charles Birch, Birmingham University and King's College Hospital; Anthony Bourchier Bradford, Durham University and St. Thomas's Hospital; Charles Bramhall, London Hospital; William Kenneth Dudolt Breton, St. Mary's Hospital; Frederick William Cheese and Noel Alfred William Conolly, St. Bartholomew's Hospital; George Brooke Forbes Churchill and Reginald Thomas Collins, Guy's Hospital; William Walter Claridge, Middlesex Hospital; James Duncan Clay, King's College Hospital; Charles Cordell, University College and Royal Infirmary, Bristol; Hugh Pennington Croly, Arthur Sydney Downton, and Thomas Scarborough Dudding, London Hospital; Charles Woolmer Davies, St. Thomas's Hospital; William James Davies, Guy's Hospital; John Thomas D'Ewart, Owens College and Royal Infirmary, Manchester; Stanley Dodd, Westminster Hospital; George Grigson Elliott, Cambridge University and St. Bartholomew's Hospital; Francis Heygate Ellis, David Haydn Evans, and Gerald Sydney Ewen, St. Bartholomew's Hospital; Charles Wesley Forsyth, Owens College and Royal Infirmary, Manchester, and University College Hospital; James Bernard Chalmers Francis, Westminster Hospital; Samuel Newall Foulkes and Philip Anthony Mark Green, London Hospital; William Gillitt, Middlesex Hospital; Charles Hebblon Gregory, B.A. Camb., Cambridge University and St. Bartholomew's Hospital; Charles Frederick Hardie, M.A. Camb., Cambridge University and University College Hospital; Maurice Willoughby Haydon and Christopher Tredwell Holford, St. Thomas's Hospital; Percy Alfred Hayne and Lawrence Charles Hunt, St. George's Hospital; Frederick Aylmer Hort, L.S.A. Lond., Cambridge University and Middlesex Hospital; David Morgan Hughes, Cardiff and University College Hospital; Edmund Octavius Hughes, St. Bartholomew's Hospital; Geoffrey Wallace Grainger Hughes, King's College Hospital; Thomas Hutchinson, Birmingham University; Charles Uncles Ind, St. Thomas's Hospital; William Watkin Cadwaladr Jones, Guy's Hospital; Gerald Ainslie Kempthorne, B.A. Camb., Cambridge University and St. Thomas's Hospital; Richard Ernest Howell Leach, B.A. Oxon., Oxford University and St. Thomas's Hospital; Harold Ashton Leth, University College Hospital; Herbert Love, Norman Macfadyen, Edward Lister Martin, and Alban Anderson Meaden, St. Bartholomew's Hospital; James Bennett McCord, M.D. Chicago, North Western University, U.S.A., and St. Thomas's Hospital; William Thomas McCowen and Arthur Orril Motta, St. Mary's Hospital; William Chisholm Macdonald, M.B., B.Ch. Edin., New Zealand and Edinburgh Universities; Anthony Mavrogordato, B.A. Oxon., Oxford University and St. Thomas's Hospital; Thomas Frederick Gisborne Mayer, London Hospital; George Whitley Micklethwait, Cambridge University and St. Bartholomew's Hospital; Ernest Henry Mulson, St. Mary's and Guy's Hospitals; Thomas Morgan, Guy's Hospital; William Herbert Neil, University College Hospital; Loraine Orton, Cambridge University and St. Bartholomew's Hospital; James Matthew O'Brien and Archibald Oates Payne, L.D.S. Eng., Charing Cross Hospital; Harold Thornbury Palmer, Guy's Hospital; Burnet Graham Patch, St. Thomas's Hospital; Fred Baily Penfold, L.D.S. Eng., Middlesex Hospital; Daniel Pettigrew, L.S.A. Lond., Sheffield, Glasgow, and University College Hospital; Harry Pierpoint, University College and Royal Infirmary, Liverpool; John Isaac Pratt, M.B. Toronto, L.C.P. & S. Ontario, Toronto University and London Hospital; Ernest George Pringle, St. Bartholomew's Hospital; Alan Carpmael Randford, William Owen Roberts, and Carrick Hey Robertson, Guy's Hospital; William Arthur Rees, Middlesex Hospital; Thomas Harper Rice, Pennsylvania, King's College Hospital and Edinburgh University; John Cecil Rix, Cambridge University and Middlesex Hospital; Christian Cathcart Robinson, St. Bartholomew's Hospital; Thomas Corrie Rutherford and Henry William Sexton, St. Thomas's Hospital; Richard Harvey Sankey, M.A. Oxon., Oxford University and St. Bartholomew's Hospital; Edward Spencer Scott and Hugh Bernard Willoughby Smith, London Hospital; Ralph Davies Smedley, Cambridge University and Guy's Hospital; Frederick Morton Vincent Smith and Clayton Warwick Smith, Guy's Hospital; James Smith, University College, Bristol, Guy's and King's College Hospitals; Hugh Ellis Stanger-Leathes, St. Bartholomew's Hospital; Frederick Joseph Stansfield, Yorkshire College and General Infirmary, Leeds; John Leeming Stephenson, St. Mungo's College, Glasgow; Basil Nelson Tebbs, M.A. Camb., Cambridge University and St. George's Hospital; Daniel Jenkins Thomas, University College, Cardiff, and Middlesex Hospital; Joseph Bernard Thompson, University College Hospital; Livesey Tong, Owens College and Royal Infirmary, Manchester; John Arthur Topham, B.A. Camb., Cambridge University and London Hospital; Edward Newbury Thornton, Charles Leonard Traylen, Moses Thomas Williams, and Geofrey Plumpton Wilson, London Hospital; Henry Charles Wales, M.B. Toronto, Toronto University; Bernard Joseph Ward, Birmingham University; Frank Ernest Welchman and Marmaduke Cordeux Wetherell, M.B., B.S. Durh., Guy's Hospital; Charles Wheen, B.A. Oxon., Oxford University and St. Thomas's Hospital; Henry Curror Williams, B.A. Cantab., Cambridge University and St. Thomas's Hospital; and Edward Allan Wilson, Yorkshire College and General Infirmary, Leeds.

SOCIETY OF APOTHECARIES OF LONDON.—In August the following candidates passed in the subjects indicated:—

Surgery.—W. Ball (Section II.), Westminster Hospital; S. Bentley (Sections I. and II.), Sheffield; A. E. Benton (Sections I. and II.), St. Mary's Hospital; G. A. Jones (Sections I. and II.), St. George's Hospital; J. D. Keir (Sections I. and II.), St. Mary's Hospital; D. E. Lockwood (Section II.), Royal Free Hospital; and A. R. McEnnery (Sections I. and II.), St. Mary's Hospital and Bristol.

Medicine.—W. Ball (Section II.), Westminster Hospital; I. Griffith (Section I.) and A. T. Harvey, London Hospital; A. R. McEnnery (Sections I. and II.), St. Mary's Hospital and Bristol; F. H. Noney (Sections I. and II.), Calcutta; C. H. Osmond (Section II.), Glasgow; and O. M. Woods (Section II.), Charing Cross Hospital.

Forensic Medicine.—W. C. P. Bremner, Toronto; A. R. McEnnery, St. Mary's Hospital and Bristol; E. H. Noney, Calcutta; H. F. B. Roberts, St. Bartholomew's Hospital; and F. O. Whitmore, Guy's Hospital and Bristol.

Midwifery.—W. Ball, Westminster Hospital; G. J. Humphreys, St. Bartholomew's Hospital; A. R. McEnnery, St. Mary's Hospital and Bristol; J. P. Nettell, London Hospital; E. H. Noney, Calcutta; S. Northwood, Birmingham; and H. F. B. Roberts, St. Bartholomew's Hospital.

The diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery:—W. Ball, G. A. Jones, D. E. Lockwood, A. R. McEnnery, H. F. B. Roberts, and O. M. Woods.

FOREIGN UNIVERSITY INTELLIGENCE.—*Algiers*: Dr. Soulié has been appointed to the Chair of General Pathology.—*Barcelona*: Dr. A. G. Prats has been appointed *privat-docent* of Medical Pathology.—*Berlin*: Professor von Leube of Würzburg has been offered the chair of Medicine held by the late Dr. C. Gerhardt. Dr. Gustav Brühl has been recognised as *privat docent* of Otology and Dr. Franz Müller as *privat docent* of Pharmacology.—*Breslau*: Dr. Victor Klingmüller has been recognised as *privat docent* of Dermatology.—*Chicago* (*Rush Medical College*): Dr. A. D. Bevan has been appointed Professor of Surgery in place of the late Dr. Fenger.—*Erlangen*: Dr. R. Fuchs has been recognised as *privat-docent* of Physiology.—*Greifswald*: Dr. Klapp has been recognised as *privat-docent* of Surgery.—*Heidelberg*: Dr. Sötbeer has been recognised as *privat-docent* of Children's Diseases.—*Marburg*: Dr. O. H. Hess has been recognised as *privat docent* of Medicine and Dr. Seemann as *privat docent* of Physiology.—*Moscow*: Dr. A. Bernstein has been recognised as *privat docent* of Neurology and Psychiatry.—*Munich*: Dr. Wilde has been recognised as *privat docent* of Hygiene.—*New York* (*College of Physicians and Surgeons*): Dr. L. Emmett Holt has been appointed Professor of Pædiatry in succession to Dr. Jacobi, resigned.—*Odessa*: The following appointments to Professorships in the new medical faculty are announced: Anatomy, Professor Batuieff of St. Petersburg; General Pathology, Professor Podvysotski; Physiology, Professor Verigo; Physiological Chemistry, Professor Medviedoff; Diagnosis, Professor Michailoff; Pharmacology, Professor Borisoff of St. Petersburg; Surgery, Professor Sapeshko; Operative Surgery, Professor Lysenkoff; Pathological Anatomy, Professor Kishenski; and Gynæcology, Professor Masen.—*Padua*: Dr. Bolognini of Bologna has been recognised as *privat docent* of Children's Diseases.—*Prague* (*German University*): Dr. Hermann Schloffer has been appointed Extraordinary Professor of Surgery. Zoja of Parma has been recognised as *privat docent* of Medicine.—*St. Petersburg* (*Military Medico-Chirurgical Academy*): Dr. Paul Avrorov has been recognised as *privat-docent* of General and Experimental Pathology.—*Vermont*: Dr. D. Shirres of Montreal has been appointed Professor of Diseases of the Nervous System.—*Vienna*: Dr. Otto Grosser has been recognised as *privat-docent* of Anatomy and Dr. Roland Grassberger as *privat docent* of Hygiene.—*Würzburg*: Dr. Burkhardt has been recognised as *privat-docent* of Surgery.

HOSPITAL SATURDAY —The amount raised for the Hospital Saturday Fund at Newton Abbot, Devon, was £130

MEDICAL MAGISTRATES —Mr J Montgomerie Alston, M D Glasg, L.R.C S Edin., and Mr James Kirkland, L.R.C P Edin., L F P S Glasg, have been placed on the Commission of the Peace for the county of Lanark

EXETER SEWAGE SCHEME —The new works which have been constructed at Exeter for the disposal of the city sewage by the septic tank system invented by the surveyor of Exeter were formally opened on August 13th in the presence of a large gathering The works are constructed to deal with the present population of 47,000 and were commenced in April, 1900 The area of the works is about four acres and they consist of six septic tanks and 12 bacterial filters The total cost of the undertaking is about £40,000

JOURNAL OF TROPICAL MEDICINE PRIZE ESSAYS ON SUBJECTS CONNECTED WITH TROPICAL DISEASES —1 A prize of the value of £10, entitled the Sivewright prize, presented by the Hon Sir James Sivewright, K C M.G, LL D, for the best article on the Duration of the Latency of Malaria after Primary Infection, as proved by Tertian or Quartan Periodicity or Demonstration of the Parasite in the Blood, has been awarded to Dr Attilio Caccini, Assistant Physician, Hospital of Santo Spirito in Sassia, Rome 2 A prize of the value of £10, entitled the Belilios prize, presented by the Hon E R Belilios, C M G, for the best article on the Spread of Plague from Rat to Rat, and from Rat to Man by the Rat-flea, has been awarded to Dr Bruno Galli Valerio, Professor in the University of Lausanne, Switzerland.

CENTENARIANS — Mrs M Short died at St Austell, Cornwall, on August 4th, at the age of 106 years and eight months. St. Austell still has a centenarian in the person of William Lemin, who was born at Warleggan, near Bodmin, in 1799 —Mrs Mary Taylor Morgan, who attained the age of 102 years on June 23rd last, died at 16, High street, Marylebone, W, on August 14th. Her last days were rendered particularly happy owing to a gracious act on the part of Her Majesty the Queen, who on August 8th caused a sympathetic letter to be addressed to the old lady and sent her a box of tea and one of the Coronation cups —The *Times* of August 20th stated that the Viscount Barbacena, a distinguished Brazilian, celebrated his hundredth birthday at Rio de Janeiro on July 20th. The proceedings included a special meeting of the Brazilian Historical and Geographical Society at which Viscount Barbacena was present and expressed his acknowledgment of the honour shown him. The British residents in Rio de Janeiro had already presented him with a gold medal on the occasion of the Diamond Jubilee of Queen Victoria He was at school in England when a boy, was present at the coronation of George IV, and in 1828 was appointed secretary of the Brazilian Legation in London under his father, the Marquis Barbacena.

THE LATE PROFESSOR LEOPOLD SCHENK —It is announced from Vienna that Dr Leopold Schenk formerly a professor at the University and director of the Embryological Institute in that city, died on August 18th Professor Schenk's name became quite a household word in 1898 owing to the peculiar views which he held with respect to the factors that determine the sex of a fœtus He considered that if the urine of a woman contained any sugar whatever even an amount so small as to be recognisable only by the phenylhydrazin reaction, there was a high probability that her offspring would be females rather than males. In order that she might have male progeny the state of her nutrition must be improved to the extent of causing the total disappearance of the sugar, the means to this end being the use of a diet in which nitrogenous and fatty components preponderated and carbohydrates were limited as much as possible Professor Schenk expounded these ideas in a book which was reviewed in THE LANCET of May 28th, 1898, p 1472. We advised expectant couples who thought of trying this system not to be over sanguine. Professor Schenk's opinions met with no acceptance in Vienna and his persistence in maintaining them led to his being removed from both the University and the Embryological Institute. He does not seem to have been daunted by the opposition his professional brethren and by his failure to make co verts, for he upheld his views in an address delivered at congress in Berlin in the summer of 1901, but the speake who took part in the ensuing discussion did not give him a encouragement.

DONATIONS AND BEQUESTS —By the will of Mi Blackman of Ramsgate, whose estate has just been prove £10,000 each are bequeathed to Guy's Hospital and the Ke and Canterbury Hospital, and £1000 to the Seamen's Hon at Ramsgate.

A NOVEL PATENT —A Swiss inventor ha patented an appliance for comparing handwritings or oth objects Its action seems to be mainly optical, it contai a mirror in part reflecting and in part transparent diagram and the specification will be found in the *Offici Gazette* of the United States Patent Office issued August 5th, 1902

DEATHS OF EMINENT FOREIGN MEDICAL MEN The deaths of the following eminent foreign medical me are announced —Dr Cesare Taruffi, formerly Professor Pathological Anatomy in Bologna.—Dr Iwan Nowack formerly Professor of Clinical Surgery in the University Moscow, at the age of 75 years —Dr Walther, of St. Peter burg Medico-Chirurgical Academy, translator of sever Russian physiological works into German, suddenly, whi on a journey in Western Russia.—Dr J Maizner formerl Professor of Midwifery in Clausenburg —Dr J Eastma Professor of Gynæcology in Indianapolis —Dr Otto Braehme of Berlin, who was a leading authority on matters co nected with railway hygiene, both civil and military H was 64 years of age and his death was due to cardia disease.—Dr Friedrich Reineboth, Professor of Medicine the University of Halle He took great interest in the bett housing of the poor as a means of diminishing deaths fro tuberculosis. He was only 35 years of age —Dr Reily Halle, the eminent anatomist and alienist.—Professor S Schenk, whose name will be remembered in connexion wit the question of the determination of sex After the di cussion referred to he resigned his chair of Histology an Embryology in the University of Vienna.

Plummer.—On August 17th, at Old Elvet, *Durham,* the wife of Selby Plummer, M.D., of a daughter.

MARRIAGES

May—Young.—On August 19th, at Havant parish church, by the Rev. E. Geoffrey May, brother of the bridegroom, assisted by the Rev. S. G. Scott, rector of Havant, Henry James May, M.B., B.C. Cantab., M.R.C.S., L.R.C.P., of Ivanhoe, Archers-road, Southampton, to Maud Landale Young, widow of the late Malcolm G. Young, Indian Staff Corps, and daughter of the late Captain Richard Cumberland, of the 7[illegible]th Foot. No cards.

Phillips—Jenkin.—On August 14th, at Landewednack church, The Lizard, Cornwall, by the Rev. L. W. Edwards, brother-in-law of the bridegroom, assisted by the Rev. C. S. Vyvyan, rector, and the Rev. P. G. Chamberlain, *Harry Harding Phillips,* M.R.C.S. Eng., L.R.C.P. Lond., of Hamilton House, Penge, to Frances Mary, third daughter of Pearse Jenkin, of Trewirgie, Redruth, and Tregullas House, The Lizard.

Thyne—Young.—On the 6th August, at Metheringham, by the Rev. J. Sinker (brother-in-law of the bride), the Rev. D. W. Barrett, M.A., rector of Chipping Barnet, and the Rev. W. Ignatius S. B[illegible]son, vicar, William Thyne, M.A., M.D., Barnet, to Kate Christian, youngest daughter of the late *Thomas Young* and Mrs. Young, of Roewath, Cumberland.

DEATHS

Gasquet.—On August 1[illegible]th, at College-gate, Brighton, Joseph Raymond Gasquet, M.D. Lond., aged [illegible] years.

Lyon.—On the 1[illegible]th inst., at 40, City-road, E.C., [illegible] Leigh, aged [illegible], surgeon. For many years in practice at [illegible]8, Barbican, E.C.

Wyman.—On August 1[illegible]th, at [illegible] Brae, Putney-hill, S.W., William Sanderson Wyman, M.D. St. And., F.R.C.S., L.S.A., in his [illegible] year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

DIFFICULTIES UNDER THE INFECTIOUS DISEASES (NOTIFICATION) ACT

To the Editors of The Lancet

Sirs —Can you tell me if a medical practitioner is entitled to his 2*s* 6*d* if he notifies a case that has already been notified by his locum tenens—that is 5*s* for the same case? This particular case was notified by the locum tenent The principal returned and notified the *same case being unaware that his locum tenent had done so* On the previous notification being pointed out to him he said that he was entitled to the fee I take it, at any rate that it is contrary to the spirit of the Act

I am Sirs yours faithfully

August 18th, 1902. X. Y Z

*** There are occasions when two certificates of notification are sent and when payment on both is due There can be no reason for a medical practitioner notifying a case already notified by the person whom he has appointed to act as his deputy but as we understand our correspondent the second notification was made by inadvertence It must be remembered that the principal being ignorant that his locum tenent had notified the case, would have broken the law and incurred a fine for all he knew to the contrary had he not made the notification We do not say that he should be paid the fee because the notification was made in good faith but we think his view should be put before the Local Government Board The interpretation of this Act constantly gives rise to difficulties as all our readers know In our issue of August 9th we stated that a house surgeon was bound to certify cases of infectious disease sent for admission to a hospital of which he was the medical officer It appears, however on reconsidering the letter of House Surgeon that infectious disease must be notified by a hospital medical officer who becomes aware of it and that he is entitled to a fee for doing so but *not* if he is the medical officer of a hospital in which *persons suffering from* infectious disease are received and is acting in that capacity According to this ' House Surgeon would notify and receive a fee if he originally discovered or became aware of the infectious disease, but he would not notify or receive a fee if another medical man had already done so and sent the patient to the hospital as to a hospital in which persons suffering from infectious diseases are received The point however is obscure and we are not aware of any judicial decision dealing with it —Ed L

HOME OR INSTITUTION WANTED

To the Editors of The Lancet

Sirs,—Can any of your readers inform me of any institution or home that would take a boy aged 13 years given to masturbation and educate him His parents are willing to pay any reasonable amount

I am Sirs yours faithfully

August 19th 1902. M D

THE ' Y" FUND

Surgeon General H S Muir begs thankfully to acknowledge additional donations towards the above Fund from Colonel A M Branfoot C I E, I M.S Major D Simpson I.M S and the following officers of the Royal Army Medical Corps Lieutenant-Colonels R H. Forman, R C K. Laffan W J R Rainsford, C I E, and S J Rennie Majors T G Lavie V H. W Davoren S Powell, H E Cree Macdonald J K. Ritchie C R Bartlett, and E Swan Marder Captains H Hewetson R W Clements, and S O Hall and Lieutenants A R Greenwood F MacLennan and A H M. Mitchell The fund now amounts to £550 It may be explained that this is in response to an appeal made privately to members of the profession for benevolent aid in a distressing case which has been described in a letter sent to a limited number of medical men (who would help the cause by kindly 'handing on" to *confrères*) Should any reader of The Lancet desire further particulars with a view to expressing *practical sympathy* a copy of the letter will be forwarded on application to Surgeon General Muir 26 Kensington gardens-terrace Hyde Park, London W

WANTED—A HOME

To the Editors of The Lancet

Sirs,—I should be obliged if you would insert the following in The Lancet as some of your correspondents may be able to assist me in the *matter* I am attending an old man aged 80 years suffering from senile dementia He is quite harmless but a great trouble to his family as he has incontinence of fæces and is constantly passing his motions about the room. Is there any inexpensive institution where he can be *taken?* I have been unable to find anything intermediate between a Poor law institution and one much above the means of my patient s friends

I am Sirs yours faithfully

101, Northcote-road, New Wandsworth S W Jas Watts
August 15th 1902

THE CASE OF DR W C RAINSBURY

To the Editors of The Lancet

Sirs —At the Nottingham Assizes on July 17th Dr Rainsbury of Skegby was sued by a collier employed at the Teversal Colliery for damages for alleged unskilful treatment of an injury to his arm sustained in November 1900 The trial resulted in a verdict for the plaintiff for £25 damages and costs It would serve no useful purpose now to enter at length into the merits of the case as judgment has been given The case was commented on in a leading article which appeared at p 228 of The Lancet of July 26th From perusal of the reports of the trial it appears that Dr Rainsbury has suffered a great hardship by reason of the judgment The expenses of defending the action were borne by the Medical Defence Union of which Dr Rainsbury is a member But by the regulations of that union it cannot pay the damages or costs which are adjudged against a defendant The judgment debt and costs amount to £182 6*s* 2*d* Dr Rainsbury has made no appeal to the Midland Medical Union for assistance but in view of the special nature of the circumstances and of the apparent injury which he has sustained the President and Council recommend that a fund be raised by subscription in order to assist Dr Rainsbury in discharging the judgment debt and costs Medical men are accordingly earnestly invited to subscribe to the fund The matter is most urgent and pressing I therefore venture to ask that donations intended to be made be sent to me at the earliest opportunity

I am Sirs, yours faithfully
George S O'Rorke,
Secretary Midland Medical Union

Albion Chambers King-street Nottingham August 13th 1902.

TWO QUERIES

To the Editors of The Lancet

Sirs,—I should feel obliged if you would give me the following information in The Lancet 1 Have the new regulations for the D.P H diploma altered those which were in force as regards the course necessary for those persons who had qualified in 1889? 2 I should feel much obliged if you would inform me where I could obtain the papers written by Professor Koch on malaria particularly those which were the outcome of his visit to Africa and the eastern world and are these papers to be obtained translated into English?

I am Sirs, yours faithfully,

August 1st 1902. Biceps

*** 1 The new rules are expressly stated not to apply to medical practitioners *registered, or entitled to be registered, on or before* Jan 1st, 1890 The rules as originally designed will be found in The Lancet Dec. 15th 1900 p 1772 while the debate upon them will be found in our issue of June 7th (p 1638) and 14th (p 1734), 1902 2. *Professor Koch s papers* appeared over a year ago in the *Deutsche Medicinische Wochenschrift*, published by Georg Thieme Leipsic. We do not know of their having been translated into English —Ed L

THE LAW FUND

TRUSTEES THE PRESIDENT OF THE ROYAL COLLEGE OF PHYSICIANS OF LONDON, THE PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND AND THE MASTER OF THE SOCIETY OF APOTHECARIES OF LONDON

The following additional subscriptions have been received by Dr Paramore 2, Gordon square, W C —Dr William Craig, £1 1*s*, Mr James Blaney 10*s* 6*d*. H. S C, 2*s* R T N, 2*s* 6*d* Dr Morton Burnett, 2*s* 6*d*

At the meeting to be held at the Holborn Restaurant on August, 1902, to present to Dr Law the results of this subscription the chair will be taken at 5 P.M

"COCOA POWDER"

Referring to our analytical notice in The Lancet of July 26th 1902, of a cocoa powder for which they are agents Messrs de Beer Brothers and Co, *of* 28 *Minories London, E C*, represent *to* us that the amount of fat found—viz 34 80 per cent —is excessive We cannot find any inaccuracy in the result, but may add that in a subsequent sample sent to us the amount of fat found was 29 70 per cent The quantity *of fat in prepared cocoas varies* between these figures according to our experience

SANATORIUMS FOR PHTHISICAL PATIENTS

To the Editors of The Lancet

Sirs,—I should feel obliged if any of your readers could inform me of any open-air sanatorium for the treatment of phthisis where a man 40 years of age could be taken in free or for payment of a small *fee*. He *is not* able to afford much, but I imagine would have a good chance of being cured were he placed under better conditions Thanking you in anticipation,

I remain, Sirs yours faithfully
W Ewart Maw

86, Carlton vale, Maida vale, N W, August 16th, 1902.

MOUSTACHES AND KISSING

To the Editors of The Lancet

Sirs —May I ask your advice? Is it not a recognised fact that a moustache is nature s filter of the atmosphere before it passes through the mouth *to* the lungs and that it absorbs and retains large quantities of noxious microbes and disease germs? I take it that this is so and that under the microscope it presents anything but an attractive group of animalculæ In these circumstances is it not more than probable that in the case of a man with a moustache imprinting a kiss on the lips of another person there is great danger that he might at the same time implant the seeds of disease and perhaps death? My object for asking these questions is that I have several children and my moustached friends are in the habit of kissing them on the lips. Should I be justified on sanitary grounds in requesting them to desist?

I am Sirs yours faithfully

August 18th 1902. PATER.

*** Kissing on the lips is to be avoided A moustache is not the completely insanitary appendage that our correspondent thinks.—ED L.

BACTERIOLOGICAL TECHNIQUE

To the Editors of THE LANCET

SIRS —I shall be glad to know if it is the usual custom in bacteriological laboratories to put Petri dishes after inoculation into a sterilised Foster s box " which is incubated with them *in situ*

I am Sirs yours faithfully

August 17th, 1902. MICROBE.

*** Though the methods of each laboratory differ considerably yet so far as our experience goes, it is certainly *not* the custom to use a Foster's box We know of no laboratory in London where such a plan is customary " the Petri dishes being placed in the incubator without any special sterilised box —ED L.

◆

Zero.—The details are not quite clear (*a*) If the discharge was for one month— discharged on trial for one month —the patient would still be under the jurisdiction of the Commissioners in Lunacy and removeable to the asylum within that period; (*b*) if discharged simply to the care of relatives—i.e., not "on trial —the jurisdiction ceases *ipso facto* and he is thenceforth as any ordinary citizen There is therefore nothing necessary 'to establish his *status quo ante* legally it is established automatically and at once. The data given in our correspondent s communication as to "the proprietor" are obscure. The term should be "medical superintendent."

Puzzled.—The question is a legal one; it is impossible to say what view a County Court Judge might take. Our correspondent is advised to consult a trustworthy solicitor

Equity—Will our correspondent kindly forward us his name and address?

G L. A —Our correspondent must consult his usual medical attendant

Medical Diary for the ensuing Week.

FRIDAY (29th).—London (2 P.M) St. Bartholomew's (1.30 P.M.) St Thomas s (3.30 P.M) Guy s (1.30 P M) Middlesex (1.30 P.M), Charing-cross (3 P.M) St. George s (1 P.M) King College (2 P M), St. Mary's (2 P.M.) Ophthalmic (10 A M) Cancer (2 P.M.) Chelsea (2 P M) Gt Northern Central (2.30 P.M), West London (2.30 P.M) London Throat (9.30 A.M) Samaritan (9.30 A M and 2.30 P.M) Throat, Golden-square, (9.30 A.M) City Orthopædic (2.30 P.M.) Soho-square (2 P M)

SATURDAY (30th).—Royal Free (9 A.M) London (2 P.M) Middlesex (1.30 P.M) St. Thomas's (2 P M), University College (9.15 A.M) Charing-cross (2 P.M) St. George's (1 P M.) St. Mary s (10 P.M.) Throat, Golden-square (9.30 A.M) Guy's (1.30 P.M)

At the Royal Eye Hospital (2 P.M.) the Royal London Ophthalmic (10 A.M) the Royal Westminster Ophthalmic (1.30 P M) and the Central London Ophthalmic Hospitals operations are performed daily

LECTURES, ADDRESSES DEMONSTRATIONS, &c.

MONDAY (25th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road W.).—3.30 P.M Dr Russell: Demonstration in Medical Wards.

TUESDAY (26th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith road, W) —5 P.M. Lecture:—Dr Ball: Throat Cases.

WEDNESDAY (27th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road W) —5 P.M Lecture:—Mr Eccles Hydrocele

THURSDAY (28th).—POST-GRADUATE COLLEGE (West London Hospital, Hammersmith-road, W) —4.30 P.M Mr Paget: Demonstration in Surgical Wards

FRIDAY (29th).—POST-GRADUATE COLLEGE (West London Hospital Hammersmith road, W).—4.30 P M. Lecture:—Dr Abraham: Skin Cases.

EDITORIAL NOTICES

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice

It is especially requested that early intelligence of local events having a medical interest or which it is desirable to bring under the notice of the profession, may be sent direct to this Office

Lectures original articles, and reports should be written on one side of the paper only AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION

Letters whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners

Local papers containing reports or news paragraphs should be marked and addressed To the Sub-Editor

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager"*

We cannot undertake to return MSS. not used

MANAGER'S NOTICES

THE INDEX TO THE LANCET

THE Index to Vol. I. of 1902, which was completed with the issue of June 28th, and the Title-page to the Volume, were given in THE LANCET of July 5th.

VOLUMES AND CASES.

VOLUMES for the first half of the year 1902 are now ready Bound in cloth, gilt lettered, price 18s, carriage extra.

Cases for binding the half year s numbers are now ready Cloth gilt lettered, price 2s. by post 2s 3d.

To be obtained on application to the Manager accompanied by remittance.

METEOROLOGICAL READINGS

(Taken daily at 8.30 a.m. by Steward's Instruments.)

LONDON SATURDAY AUGUST 30 1902

An Address to Students

Year by year as the autumn comes round, anxious thoughts are roused in many breasts by the approaching opening of the medical schools on October 1st. Old students anticipate their return to work, some with pleasure, others with regret, while those who are about to enter upon their medical career are for the most part stirred by hopes fears, and ambitions. Some drift into what is to be their life s work almost involuntarily their choice having been determined by the will of a parent or guardian , some obey a pronounced predilection ; others become medical students as the result of chance—sometimes of happy chance and sometimes the reverse. The motives leading to the choice of a career are very various but of course the primary one is the necessity which comes home to the majority of earning a living. As to those which specially influence men to enter the medical profession we are indebted to Dr ARTHUR KEITH of the London Hospital, lecturer on anatomy in the London Hospital Medical School, for a most interesting inquiry as to how 100 men at his hospital came to take up medicine as a means of livelihood. The result of Dr KEITH s inquiry which took into account men of all sorts, qualified and unqualified, some of them teachers, most of them students appeared in the *London Hospital Gazette* and his analysis showed that ' seven had their profession chosen for them 30 were born in the profession and grew up in it , 10 adopted it as a boyish ideal at a very early age , 12 adopted it by a process of exclusion—it was the profession they had the least objection to seven chose it because it was the nearest akin to their favourite subjects—zoology or chemistry 31 were led to adopt medicine from some accidental circumstance ' while ' three drifted into it—[they] could not tell why

But whatever the motive whatever the circumstances determining the adoption of medicine as a career whether from the love of humanity and the wish to alleviate suffering or because it promises the best prospect of giving some leisure hours to a favourite branch of natural science, or simply as being what the chooser thinks the preferable means of obtaining his daily bread—all men agree that when followed honestly and with a true heart it is the noblest of secular callings. So that those who find themselves in it as the creatures of circumstance, or drift into it they know not why may be happy in the thought that they have chosen an excellent career In early life it is somewhat rare for a lad to have any very definite ideas as to his future. The real work of life seems to all but a few lads in whom environment or an innate seriousness has implanted an unusual sense of responsibility so vague and distant that they do not regard it with any particular gravity Anxiety is generally absent, though hope may irradiate the path before them with the golden light of fancy which, alas, as they press onward, is too apt to fade away Yet Dr KEITH'S analysis shows that 10 out of 100 medical votaries resolved to take medicine as their profession when aged only six or seven years. It is interesting to learn that these 10 children made no mistake in their precocious choice of a profession, for all of them have proved successful or are in a fair way of becoming so. This group of early devotees to medicine might probably have been enlarged as Dr KEITH suggests, from the 30 who were born in the profession. The son of a medical practitioner who sees his father beloved and notes the position of delicate responsibility that he holds in the neighbourhood is very likely to wish to enjoy the same privileges. The father whose professional career has brought him the sweets of success, is certain to encourage in his son any early desire that may appear to follow in the parental footsteps

But although chance plays so large a part in determining the choice of a career among medical students the medical profession is by no means one that should be lightly entered upon. To become a legally qualified practitioner is to-day a more arduous undertaking than it was 40 or even 20 years ago A curriculum involving five years of hard work with its multitude of subjects to be got up " for examination, each one of them important enough to occupy the best years of a man s life, shows clearly enough that, however it may have been with the heroes of the famous novels by DICKENS COCKTON and ALBERT SMITH *the medical student of to-day has no time for* idleness. From the first day of October the man who would be successful, not merely in passing his examinations but in obtaining such a preparation as will make him worthy of the confidence and respect of his patients and of the honourable competence he hopes to secure must make up his mind to lead a diligent and even a laborious life. Not that he has any need to be a melancholy man. The secrets of abstract lore can be wrestled with in sad solitude, but a profession that requires a knowledge of life and a sympathy with all forms of human ill is not to be thoroughly mastered by a recluse. The attitude in which a man approaches his work is not wholly a matter upon which he can exercise free will, for it must depend, of course, somewhat on his natural temperament but, assuming that he is working steadily he has the right to cultivate a cheerful way of looking at things and to take every opportunity of exchanging his experiences with his fellows that he may gain the breadth of opinion and charity of view so essential to the medical practitioner The student s optimism need not be of the exaggerated variety but it should spring from the consciousness that he is doing his duty by making the best efforts that he can to master each day s work as it comes before him feeling sure that regular labour means regularly progressive results.

If there is one virtue more than charity which the medical practitioner and therefore the medical student, must make his own it is self management—the power to order the scheme of living in accordance with what produces the best working day To cultivate habits of regular study properly interleaved with regular exercise should be one of the first aims of the medical student. When he is master of his methods of work, even though he starts slowly, he will find that he is surely ascending the hill of knowledge And a slow start is not a bad thing, as we all know from experience as well as from proverbial teaching Mountains cannot be ascended with a rush, but by climbing patiently, little by little, the end is achieved Medical studies must, the student will find, be planned out systematically, according to the requirements of the curriculum, while the counsel of his teachers will be readily given on all points as to books for private reading and courses of practical work. In the days to which some of us can look back aids to study were very different, and as the curriculum was much simpler so the establishment provided by a medical school for students was much more meagre Even 20 years ago the chemical laboratories then to be found were very primitive and incompletely equipped. Physiological and pathological laboratories scarcely existed. There were no facilities for bacteriological research, for bacteriology was not merely an unexplored but an unknown continent. PASTEUR and LISTER were great names to the medical student, but in the seventies and early eighties they were but names. He learned in books and lectures the enormous significance of their work, but he had no practical lot in it. Now every medical student is required to make himself thoroughly familiar with such simple bacteriological procedures as may be called for from him in his after professional career if his patients are to enjoy the benefits of recent research

It is well, we think, that parents should realise more clearly than was formerly required of them how exacting a career their sons have embarked upon and how easily a temporary failure may follow upon honest endeavour For if the facilities for learning have enormously increased the multiplicity of subjects now embraced in a medical education has magnified the difficulties of the student in proportion. The subjects for study being so numerous and their extent so great, a feeling almost of despair may sometimes arise in the student's head He fears that he will not be able to master them in the allotted time, and when a young man thinks that he cannot get through a certain amount of work in such a huge space of time as five years appear to him it may be taken for granted that his feelings of anxiety are very real. They are often so real that he may be tempted to put aside his medical ambition and turn to some other calling where not so much will be required of him. To our younger readers, who are now about to begin their medical careers, we would especially say that when they feel in this despondent mood is exactly the time when they should try the magic recipe of orderly restrained work in accordance with a laid-down plan. Let them make a vow and keep it that within a certain time some small province of knowledge shall be annexed With conquest will come the lust of conquest, with the habit of work will come skill in working, so that they will be able instinctively to plot out their time, whether in the medical school or in their rooms, to the best advantage In a very short space of time depression will be removed and confidence restored. The student should take care to complete each day's task as it comes and to review systematically what he has done, so as to secure the steps that he has already made

We hesitate to recommend the student to limit his work strictly to the curriculum, although if he should have occasion to seek the help of any private tutor that is the first advice that will be given to him But it is not good to aim too low, to attempt to acquire the minimum knowledge necessary for passing Students who do this run risks of missing their mark and rarely acquire any true interest in their pursuits. It is necessary to strive to know fully and thoroughly the various subjects required for examination, but if medical practice is the student's aim it will be cautious to watch against misplaced zeal. While it is unwise to try to enter on a medical career with the scantiest possible equipment, it is equally unwise to start in that career loaded with unnecessary baggage There is a mean to be preserved What is required by the curriculum should be known thoroughly, but before the student seeks to specialise in one of the ancillary sciences he should realise that in doing so he may be wasting his time. The preparatory subjects in modern medical education are so fascinating that to a man fond of chemistry, for example, there is a danger of being led astray and of following its tempting by paths to the detriment of other studies. TROUSSEAU, we believe, said that medical men are *tristes chimistes*, but we have known students waste a great deal of time, which ought to have been otherwise employed, in developing a taste for chemistry which conducted them nowhere, not even to any real knowledge of their favourite subject. In the same way the subjects of minute anatomy, physiology, and biology afford vistas so attractive that the young philosopher may yield to their charms and follow them beyond the limit that prudence indicates For it is clearly, or ought to be, the purpose of the serious student to obtain a knowledge of the various branches of his profession as full and accurate as possible during the five years of the medical curriculum If this is to be done successfully there will not be much time for excursions In these days specialisation has become a fashion, and indeed the continued growth of knowledge in the various branches of medicine and surgery makes it almost unavoidable if any one branch is to be followed beyond the threshold. But the time for becoming a specialist is, at any rate, not during the period of medical studentship The best thing to do, whether medicine, surgery, or gynæcology is the aim, is to become a well-equipped all round man before picking, or drifting into, some special branch of practice. And even then prudence may suggest delay unless there are private means sufficient to tide over the period of waiting—often the weary hopeless waiting—for opportunity and success But for the encouragement of the average student it may be said that the possession of fair mental endowments, with steadiness and determination of character, are more valuable than a supposed gift of genius—a gift, by the way, which it is rarely safe for even the youngest of us to imagine as his own The steady worker will not, as a rule, be left far behind the erratic genius

There is one respect in which a lad who in the old days had chosen, or had been chosen for, the calling of a medical man had some initial advantage over the student of to-day He had an opportunity as an apprentice of acquiring a rough preliminary knowledge of his professional subjects that is now denied him until he is actually enrolled in a class at a medical school. In the days of apprenticeship to a general practitioner a conscientious master would usually aid his pupil by introducing him to the elements of anatomy The pupil also learned to dispense and became familiar with materia medica as it was known at that time. And he gradually became acquainted with what may be called the routine of practice. Such measures as come under the head of first aid he grew familiar with and he was often taken to interesting cases to give some help in or to watch operations and to see cases of midwifery Perhaps of more value still to him afterwards, he became acquainted with men, women and children as patients while if his master were a gentleman of kindly feeling he had invaluable lessons in the art of dealing with suffering humanity of sympathising with and encouraging the nervous and despondent, of firmly and quietly controlling the wayward, and of taking into the sick room an atmosphere of cheerfulness and hope. He learned also to respect the confidences of patients and to practise that golden rule of medical ethics—to keep silence as to their weaknesses and ailments. All this was, of course, preparatory to entry at a medical school before as the phrase was, the student began to walk the hospitals" This familiarity with medical matters, though acquired in a haphazard and desultory manner was often of value, not only later in commencing private practice, but also in enabling the student to apprehend many things in hospital work which would have been strange and unfamiliar to one fresh from school or college. There are students who have the strongest objection to being convicted of complete ignorance in front of their fellows. This may imply vanity, but vanity is a failing from which no class of young men is exempt, or it may mean shyness. Such men shirk demonstrations lest they should be asked questions and do not themselves seek information because they do not desire to betray their complete lack of it To such students the system of apprenticeship was peculiarly valuable. By the time that they began to pit themselves against their fellows their shyness was gone and they had a certain familiarity with their subjects. However the system of apprenticeship is dead and this is no place to discuss its merits and its demerits. Our concern is to give a few words of counsel to the student on the threshold of his career and this seems a convenient place to urge upon him the value of curiosity Let him always ask questions Let him never fear to display ignorance. Let him never be ashamed to attract attention by wanting to know As a rule, he will find that his inquisitive attitude is recognised at once as the right one by his teachers and his more sensible fellow students. It must be remembered that though guidance will be freely given such help does not lessen the amount of work that the student must do to make the knowledge acquired his own. Lightly come lightly go" is true of knowledge as well as of money and what is easily learned by asking a question is easily forgotten unless pains are taken to retain it. And so we get back to the point that we have already made, that medical knowledge can only be acquired by careful mapping out of the ground, by systematic advance and by frequent revision Steady diligence is needed to master the many subjects and the great detail of a medical education

And here the question arises as to how many hours a day should be given to work. No answer is applicable to all cases, but as a general statement better work is done in eight hours than in a greater number and if the attention is given closely they are as many as most students can bear without injury to health. Men are often said to work 12, 14 or 16 hours a day, but such diligence cannot be kept up long if there is really any concentration of mental force. These debauches of study are habitually indulged in by those who have been slack and want to cram their subjects for an examination but they seldom help the student much in his desire to cheat the examiner into that proof of diligence, a pass-certificate Eight hours work is a high average for any man to maintain, and the student who approaches it nearly will not find much trouble in satisfying his examiners while such diligence will show that his subjects appeal gratefully to him And while storing the mind it does not answer to neglect the body a due proportion of time must be given to sleep, to meals, and to recreation. The old division of the 24 hours into eight hours for sleep, eight for work and eight for meals and recreation has never been much improved on Nothing is more important than a due proportion of sleep. Exercise is necessary for health but the student must use discretion as to its amount. There are obvious dangers in excessive devotion to athletics but the medical student at a school situated in a town is not exposed to them in the way that the lad at the university or one of the public schools is exposed to them. The medical student, if he is a student in anything more than name, will not be able to give up whole days week after week to games, he will not be able to play any game regularly or often. The value of games such as cricket or football is increased by the discipline required of their exponents by the need for learning how to work with others for a common object. There is no fear that the genuine medical student will ever sink into the mere devotee of athletic against whom Mr RUDYARD KIPLING has waxed so wroth. The genuine medical student has only occasional hours to spend away from his work, but when those hours come we advise him to use them in hardening his muscles and cultivating his self-control in the mimic strife of games

The medical life like every other, has its pleasures and its pains and the latter cannot be disregarded. It is not likely that the student has reckoned up the troubles or that he will pay much heed to them when we allude to them. Nothing is further from our wishes than to discourage him, but we have a reason for wishing to allude to the circumstances that make the medical practitioner's life often a hard one. And in many respects it is a very hard one, while the pecuniary reward is comparatively small. A few large incomes are made and a few titles gained but the great majority must be content with a moderate competence. The complete immunity enjoyed in this country by quackery and the system of contract payment under which medical men are grossly sweated are the two factors which combine to make our arduous and responsible calling so poor a calling from the pecuniary point of view. And the reason why we think it opportune to point this out to students is as follows. Many of the drawbacks to the medical life spring from want of professional union. If the medical profession were at one upon the questions which concern their professional welfare, if they were not apathetic, and especially if the leaders of medicine would show practical interest in what are termed medical politics, reforms—and not only trivial but important reforms—would follow in large number. The student of to day is the practitioner of to-morrow and, if he have the proper making and the fitting opportunities, the leader of a few years later. Hence we wish to impress upon the student that he should be ready when his time comes to combine with his professional colleagues in securing for himself and them proper recognition of the services to the community discharged by medical men, and that he should not consider medical politics a subject in which it is a little undignified—say, a little tradesman like—for him to be interested. The student cannot too early be taught that it will be as a medical man his duty to study medical politics and to help his professional brethren to an understanding of them, while we can assure him that by the effective union of the profession that would follow such understanding most of the difficulties that now beset the general practitioner's path would be removed.

And having frankly alluded to the drawbacks of the medical profession as real in the present, however far they may be removeable in the future, let us conclude none the less by congratulating our recruits upon having enlisted among us. Though many causes are at work, such as the prevalence of quackery, the abuse of hospitals, the medical aid societies that sweat the medical man, the keen competition in a crowded profession, which all tend to lower medical incomes, a modest return may always be counted on and some of the fortunate ones may look for more. And though the work is often hard, and busy days are followed by busy nights, there are rewards of infinite sweetness. What though the medical man occasionally meet with meanness, rudeness, and ingratitude. These things are not the rule, and to no other body of men is it given so often to deserve the heartfelt thanks of their fellows, to be brothers to the weak and helpers to the fallen. And apart from the grand feeling that merely to do the duty of the day is to discharge functions of the greatest gravity and cope with situations of the most delicate responsibility, the practice of medicine has intellectual fascinations that are surpassed in no walk of life. No other pursuit can equal ours in variety and interest, and when followed conscientiously none will bring to the mind so unalloyed a sense of pleasure.

And so we bid welcome to those who this year reinforce our ranks. If they are of the right stamp they have chosen a life which for all its hardships has many counterbalancing charms, especially for those who can learn to value the peace of mind that a well-spent life will surely bring, and can pray with sincerity as a wise man once prayed "Remove far from me vanity and lies, give me neither poverty nor riches."

THE STUDENT'S LIBRARY

WE have for many years been in the habit of suggesting for the benefit of the medical student a list of books which he will find useful in the course of his professional career. This list was originally designed to be helpful to him in a choice of the treatises which he should read before he can hope to obtain a place on the Medical Register. Of late years the making of this list has become very difficult. Many new books have been written and a great general advancement in certain valuable qualities has been imparted into their writing. The English medical text book of modern days has become as orderly as its French and German predecessors were wont to be, and an effort has been made all round towards perfect clearness. We have had few books where the teaching was not founded upon the practical knowledge of the author and where the lessons which the author desired to convey have not been definite and intelligible. The purely book making treatises have been to a considerable extent of American manufacture, but in saying this we must not lose sight of the fact that to American enterprise, industry, and erudition we now owe an extensive medical literature. In particular do the authors and publishers of the United States excel in the production of great dictionaries, and encyclopædic compilations of monographs by many writers. From these three things—the large supply of text-books, their excellent and authoritative nature, and the addition of many valuable American works to our library—arises a great difficulty for anyone who should attempt to suggest to the student what should and what should not be the book he ought to buy. The reviewers in our columns have reported equally well upon two or three different text-books of surgery and two or three different text-books of medicine, and in the more special branches of professional knowledge it is even more difficult than when dealing with comprehensive treatises to say which book *par excellence* should be recommended to the student. Year by year we have found our list of recommended books growing larger and larger. Our knowledge that in many cases there was almost nothing to choose between works from the standpoint of their efficiency led us to include several written with the same purpose and scope rather than to exercise an opportunity of choice that would appear to have been taken invidiously. The list at length became unwieldy, and we have lately adopted an entirely different plan.

BOOKS RECOMMENDED FOR THE DOUBLE QUALIFICATION OF THE ENGLISH ROYAL COLLEGES.

We have taken the examinations for the double diplomas of the Conjoint Board of the Royal College of Physicians of London and the Royal College of Surgeons of England as the type of the tests which every student works to pass. He may not do so much and he may do more, the above mentioned qualification is a good representative one. The following are the text-books that are recommended by the consensus of opinion of a well known group of London teachers for the examinations of the London Conjoint qualification, the list being almost identical with the one which we published in the Student's Number last year:—

FIRST EXAMINATION

Chemistry.—LUFF'S *Chemistry*; Cassell, 7*s* 6*d*.—This book was written with a view to this examination and contains exactly the right material. ATTFIELD'S *Chemistry* (Gurney and Jackson, 15*s*.) is also recommended. It is in its seventeenth edition. A new edition of DUPRÉ and HAKE'S *Inorganic Chemistry* (C. Griffin and Co., 9*s* net) is also specially adapted to the needs of medical students. Third edition.

Physics.—DANIELL'S *Physics*, Macmillan and Co., Limited, 4*s* 6*d*.—ALDOUS'S *Physics*, Macmillan and Co., Limited, 7*s* 6*d* —The student will only require selections which should be made in accordance with the advice of his teachers.

Pharmacy.—HALE WHITE'S *Materia Medica* J & A. Churchill, 7*s*. 6*d* A new edition (the seventh) was published this year

Biology.—P CHALMERS MITCHELL'S *Outlines of Biology* Methuen, 6*s*.—The book was written with a view to this examination but we strongly recommend the medical student of the present day to extend his biological reading if only in a desultory manner to the works of among others, HUXLEY and BEALE

SECOND EXAMINATION

Anatomy.—GRAY'S *Anatomy* Longmans, 32*s* net.—QUAIN'S *Anatomy* Longmans, in nine parts at different prices.—MORRIS'S *Anatomy* A new edition (the third) will be issued in time for the Autumn Session. J & A Churchill, 36*s*.—The first of these treatises is sufficient by itself, while the article in it upon osteology is unequalled. The books of QUAIN and MORRIS contain matter that is not essential for the examination under consideration, but all who aspire to the honour examinations must have and read them. The same may be said for the *Manual of Practical Anatomy* by the late Professor ALFRED HUGHES and Dr ARTHUR KEITH which is now completed (J & A. Churchill Part. II and Part III published this year 8*s* 6*d* and 10*s* 6*d* respectively)

Physiology.—HALLIBURTON'S *Kirkes Physiology* (fourth edition) J Murray 14*s*.—The omission of FOSTER'S *Physiology* here may strike some as extraordinary It is the best text-book in English and written in perfect literary style, but it does not supply the medical student with sufficiently cut-and-dried answers to questions which are sure to be set him at this examination. HALLIBURTON'S *Kirkes* is therefore the book to be recommended for the average student, but by all means let him enlarge his knowledge by reading FOSTER'S or STEWART'S book if he finds that he can swim in deeper water.—HALLIBURTON'S *Chemical Physiology* Longmans 28*s*.—SCHÄFER'S *Course of Practical Histology* Smith and Elder 7*s* 6*d*.—SCHÄFER'S *Essentials of Histology*, Longmans, 8*s*.—BRODIE'S *Essentials of Physiology* Longmans 6*s*. 6*d*.—These four books should be read to supplement HALLIBURTON'S *Kirkes Physiology*

THIRD EXAMINATION

Medicine.—OSLER'S *Principles and Practice of Medicine* (fourth edition thoroughly revised) Henry Kimpton, 18*s* net.—A clear and well arranged book perfectly up to date. It has taken the place of that admirable book, BRISTOWE'S *Theory and Practice of Medicine* which has now fallen a little behind the times.—TAYLOR'S *Manual of the Practice of Medicine* J & A. Churchill 16*s* All students who can afford it should possess this book too.—CARTER'S *Elements of Practical Medicine* will serve as a sound foundation a new and thoroughly revised edition was issued recently H. K. Lewis 10*s* 6*d*

Applied Anatomy.—TREVES'S (Assisted by ARTHUR KEITH M D) *Surgical Anatomy* (new edition, Cassell) 9*s*.—HOLDEN'S *Landmarks Medical and Surgical* (J & A. Churchill, 3*s*. 6*d*) also thoroughly deserves the popularity it has so long enjoyed as a book on applied anatomy while the supplementary volume on Surgical Anatomy in QUAIN'S *Anatomy* by THANE and GODLEE (Longman 6*s* 6*d*) is excellent.

Pathology.—GREEN'S *Pathology* Renshaw 17*s*.—LAZARUS BARLOW'S *General Pathology* J & A. Churchill, 21*s*.—BOWLBY'S *Surgical Pathology* J & A. Churchill, 10*s* 6*d*.—CURTIS'S *Essentials of Bacteriology* Longmans 9*s*.—Of course it will be well if the student can find time to read the larger works of Crookshank and Sternberg

Materia Medica.—MITCHELL BRUCE'S *Materia Medica* Cassell 7*s* 6*d*

Forensic Medicine.—LUFF'S *Forensic Medicine* Longmans 24*s*.—AUBREY HUSBAND'S *Forensic Medicine* Simpkin 10*s* 6*d*.—Both books fit the examination but we recommend the student also to read the larger treatises by TAYLOR and STEVENSON (J & A. Churchill, 31*s*. 6*d*) or DIXON MANN (C Griffin and Co, third edition 21*s*) Forensic medicine is interesting reading so that a big book should have no terrors.

Public Health.—PARKES and KENWOOD'S *Hygiene* second edition in September Lewis 12*s*.—This book is based on Dr Louis Parkes *Hygiene* fifth edition. WHITELEGGE'S *Hygiene* Cassell, 7*s* 6*d*.—Each of these books is good and contains more than is required for the examination.—*A Book of Hygiene* (C Griffin and Co Limited 8*s* 6*d* net) by A M DAVIES, Lieutenant-Colonel R.A.M C. is also a most useful and comprehensive treatise.

Surgery.—ROSE and CARLESS'S *Manual of Surgery* Baillière Tindall and Cox, 21*s*.—This book contains all that is necessary for the examination, and has been regularly kept up to date but a student with any ambition will supplement his reading by consulting one of the three more comprehensive treatises which follow He must also read JACOBSON'S and STEWARD'S *Operations of Surgery* (J & A Churchill 42*s*) or TREVES'S *Operative Surgery* (Cassell 42*s*). A fourth edition of JACOBSON'S and STEWARD'S work is issued this year.—ERICHSEN'S *Science and Art of Surgery* (Longmans, 48*s*) TREVES'S *System of Surgery* (Cassell, 48*s*) and TILLMAN'S *Surgery* (Kimpton, 63*s*) must be consulted as books of reference, while every student will find SPENCER'S *Outlines of Practical Surgery* (Baillière, Tindall, and Cox, 12*s* 6*d*.) of great help to him.

Midwifery.—GALABIN'S *Midwifery* (J & A. Churchill 15*s*) or DAKIN'S *Midwifery* (Longmans 18*s*) is most exactly fitted for this examination. In Gynæcology we recommend, as on previous occasions LEWERS'S *Diseases of Women* (Lewis, 10*s* 6*d*)—HERMAN'S *Diseases of Women* (Cassell 25*s*) and HERMAN'S *Difficult Labour* (Cassell, 12*s* 6*d*) should also be read.

The student should also read HARE'S *Practical Diagnosis* fourth edition (Kimpton 21*s* net) which explains the use of symptoms in the diagnosis of disease. This book will, of course only be valuable to those in the fifth year of the curriculum but to them it will prove very useful and suggestive He must also read a Text-book of Ophthalmic Surgery SWANZY'S book (Lewis 12*s* 6*d*) is suggested as containing all that he is required to know He should also read MALCOLM MORRIS'S *Diseases of the Skin* (Cassell 10*s* 6*d*) and a *Manual of Bacteriology* by HEWLETT (J & A. Churchill, 12*s* 6*d*.). With regard to the literature of bacteriology the student will probably be required by his teachers to use certain text books and our recommendation is not intended to supersede their advice The student must work in accordance with his class mates.

This does not seem a very large library for a working man to read in a curriculum extending over five years but if the books are read properly they will amply suffice For they have to be thoroughly mastered and completely assimilated All passages in them not perfectly clear at the first or even the tenth reading must be made so ultimately if there is to be no doubt about the result of an examination, and from the first word to the last of every book it must be treated as the handmaiden of practical work. Now it should indicate how to begin practical work, now it should explain practical processes and now and most frequently it should form a *memoria technica* whereby practical lessons learned in the dissecting room the laboratory or the ward can be recalled in a moment either for practical or examination purposes

THE BOOK AND THE STUDENT

As we have often had occasion to point out the uses that different students are able to make of books vary so much with their order of mind that no [illegible] library can ever be the best possible library for all [illegible] one man the elementary [illegible] may be [illegible] reading. He will be able to use it as the skeleton of his knowledge and will endow it with tissues and life from his personal observation, by practical courses in his school, by clinical work in the wards, and by thoughtful attendance at lectures. This is the student into whose work books do not largely enter. But inasmuch as it is easy to examine fairly and thoroughly upon book-work, while it is difficult to lay down proper standards and discover adequate tests for the appraisement of practical work the result of examinations must more or less depend upon the ability of the student to answer somewhat in text-book language questions framed somewhat upon text-book lines. Therefore it will be well for the student whose practical order of mind enables him, as it were, to write his own text-book by grafting his practical work on to an elementary manual, to revise his knowledge before entering for an examination by the light of a first-class text-book. This is the best and most feasible way of combining books and practical and clinical work for the formation of a medical education. But it is not in the power of every student to obtain an education in this manner. Practical work is easier to some men than to others, and lectures mean more to some men than to others. The receptive man will benefit by teaching, which only arouses opposition in the critical man. The reading of a large text-book by the critically minded man—the man whose first impulse on hearing a fact is to doubt it or the deductions from it—may very often be the best way in which such a man can gain a knowledge of his subject. He gets an all round look at it, and though he may not entirely understand everything that he reads he will obtain a general familiarity with the topic and see the fallacy of the objections which rise in his mind. The bald statements for which alone the small manual can find room arouse in him nothing but opposition, and he will be well advised to go straight to the big book where the explanations are included with the facts. But he *must* supplement his wider range of reading with as honest and as earnest a course of practical work as his less literary fellow students. When confronted with examinations he will find, as hundreds of the most promising students of medicine have found to their considerable discomfiture, that practical work is absolutely necessary, that without it book-work is as nothing, that even to pass in the written part of the examination (for which he feels so amply equipped) will be almost impossible unless his knowledge is fortified and made alive by some measure of practical experience, and, lastly, that no amount of book-work will ever enable him to answer questions by word of mouth.

BOOKS RECOMMENDED FOR THE HIGHEST QUALIFICATIONS.

The list of books given above as necessary to be read before the student can make certain of obtaining the diploma of the Conjoint Board will if absolutely mastered go very far to take him through any honour examination—especially if his practical work be good and if he have an orderly mind and a ready wit, so that he is at his best during his tests, but in certain directions the aspirant for the medical degree of the University of London and the Fellowship of the Royal College of Surgeons of England must read more advanced works. The degrees of other universities, especially those of Oxford and Cambridge, will also require from their candidates a larger range of reading, but in these it is chiefly for the final examination, the standard of which is (or is expected to be) higher than the standard of the pass examinations of the various corporations. In the case of London University the increased stringency of the tests is felt from the beginning, while the first examination for the Fellowship of the Royal College of Surgeons of England is one of the hardest and most uncertain examinations known to us. In making the suggestions which follow we premise in the student a complete knowledge of the simpler works.

For the Preliminary Scientific Examination of London University RIDEAL'S *Practical Organic Chemistry* (Lewis, 2s. 6d.), TILDEN'S *Inorganic Chemistry* (J. & A. Churchill, 10s.), REMSEN'S *Organic Chemistry* (Macmillan and Co., Limited, 6s. 6d.), and BERNAYS' *Practical Chemistry* (J. & A. Churchill, 4s. 6d.) are recommended. DANIELL'S *Text book of Physics* (Macmillan and Co., Limited, 21s.) should be supplemented by DESCHANEL'S well known volumes and such books as CATCHPOOL'S *Sound* (Clive, 3s. 6d.), LOWSON'S *Botany* (Clive, 6s. 6d.), and WELLS and DAVIES'S *Zoology* (Clive, 6s. 6d.). MUDGE'S *Biology* (Arnold and Co.) is a book which is intended exactly to fit the needs of this examination, while the course of botanical reading should include SCOTT'S *Structural Botany* (Adam and Charles Black, two vols., 3s. 6d. each). For the first M.B. of the University of London and for the first Fellowship of the Royal College of Surgeons of England MORRIS'S *Anatomy* (J. & A. Churchill, 36s.) is, on the whole, the best text book, but the student should also read Embryology by SCHÄFER and Splanchnology by SCHÄFER and SYMINGTON in QUAIN'S *Anatomy* (Longmans, 9s. and 16s. respectively) and revise his osteology from time to time by GRAY'S *Anatomy* (Longmans, 36s.) and his practical work by CUNNINGHAM'S *Practical Anatomy* (two vols., Young J. Pentland, 12s. 6d. each) or BRODIE'S *Dissections Illustrated* (Whittaker and Co., 42s.). Professor CUNNINGHAM has also published this year a splendid *Text-book of Anatomy* (Young J. Pentland) written by himself and nine other competent contributors. The book is profusely illustrated with original drawings and much in it which deals with the topographical relations of the viscera departs considerably from convention. This is a book from which the able student can derive much suggestive information. For both these examinations STEWART'S *Physiology*, fourth edition (Baillière, Tindall, and Cox, 15s.) or FOSTER'S *Physiology* (Macmillan and Co., Limited, in four parts, 10s. 6d. each, and appendix, 7s. 6d.) should be read.

For the final medical examinations of the great universities no different text-books are absolutely required to those suggested for the final examination of the Conjoint Board, but the student's reading should be regularly supplemented by studying the valuable monographs in ALLBUTT'S *System of Medicine*, the pages of the medical journals, and such works as POWELL'S *Diseases of the Lungs and Pleura* (Lewis, 18s.), GOWERS'S *Treatises on Neurology* (J. & A. Churchill, vol. i., 15s., vol. ii., 20s.), VON JAKSCH'S *Clinical Diagnosis*, fourth English edition (Griffin and Co., 24s.), and JUDSON BURY'S *Clinical Medicine*, second edition (C. Griffin and Co., 21s.). A sound knowledge of bacteriology will also be expected of the medical graduates of the principal universities, who will be expected to be familiar with the modern views of the etiology and prevention of infective diseases. STERNBERG'S *Bacteriology* and CROOKSHANK'S *Text book of Bacteriology* (H. K. Lewis, 21s. net) are the best modern works. For the final surgical examination of the University of London (that for the degree of M.S.) and for the final F.R.C.S. the first thing for the candidate to remember absolutely is that his anatomical knowledge must be as perfect as it was at his previous tests. If it be taken for granted that the student has a thorough knowledge of such a text-book as that of ROSE and CARLESS, then the book to read is TILLMANN'S *System of Surgery* (Kimpton, 63s.). The book is thoroughly well written, comprehensive, and completely up to date, which can no longer be said of HOLMES'S *System* or even of ERICHSEN'S splendid work. *A Manual of Surgical Treatment*, by W. WATSON CHEYNE and F. F. BURGHARD, has been issued in parts at prices varying from 10s. 6d. to 18s. by Longmans. This is a valuable work, sound, practical, and up to date, and the same may be said of WALSHAM'S *Surgery* now in its seventh edition (J & A. Churchill, 15s) Such monographs as those by BLAND-SUTTON on *Tumours* and on *Ligaments* (H K Lewis, 4s 6d) by TREVES on *Intestinal Obstruction* (Cassell and Co., 21s) by TUBBY on *Deformities* by MORRIS on the *Surgical Diseases of the Kidney and Ureter* (Cassell and Co. 2 vols 42s net.) by WARING on *Operative Surgery* and by MARSH on *Joints* should also be read

RECENT MEDICAL LITERATURE.

During the past student's year some excellent works have appeared which have been highly reviewed in our columns but which cannot be called essential to the library of the student A certain proportion of these text-books have been and will be, read by very many students and if they are kept up to date where necessary will very possibly take the place in popularity of those now occupied by other works. A text-book in these days of medical progress requires almost annual revision explanations once necessary become no longer, so new discoveries entail large additions, doubt is thrown upon accepted theories importance is given in the medical curriculum to subjects which had previously been barely noticed, and so on. From any or all of these reasons a book that is to appeal to students from year to year must be revised almost annually It follows from this that text books which we now recommend as essential—as far as any one text book can be essential to the student's education—may easily drop behind and its place be taken by another book more carefully brought up to date and more *directly written to suit the immediate exigencies of the* Examination Board

A new edition has recently appeared of FAGGE'S famous *Text-book of Medicine* the book being entirely revised and largely re-written by Dr P H PYE-SMITH (J & A. Churchill, 21s.) FAGGE'S work is almost the only text-book of its kind which at the present day presents the clinical aspect of disease in a style which SYDENHAM—that great master of descriptive medicine—would have approved. A second edition of the valuable treatise on Surgery edited by Dr ROSWELL PARK which was published a few years ago has also appeared during the year (*A Treatise on Surgery by American Authors for Students and Practitioners of Surgery and Medicine* edited by ROSWELL PARK. Henry Kimpton, 25s) It was felt that the book in its original form was rather large and expensive for the average practitioner or student, and therefore it was decided to issue a smaller edition while at the same time the opportunity has been taken of revising numerous points The chief effect of *the contraction of the size of* the treatise has been *to* make it more readable and more handy in use

Quain's Dictionary of Medicine by Various Writers has also made another appearance, the third edition being largely re-written and revised throughout under the editorship of Dr MONTAGUE MURRAY assisted by Dr JOHN HAROLD and Dr CECIL BOSANQUET (Longmans, Green, and Co. 21s). Quain's Dictionary of Medicine continues to be a wonderfully comprehensive encyclopædic work. It is well illustrated and well arranged for facility of reference and the practitioner and student of medicine will assuredly find it of great practical value as a trustworthy and available book for the purpose alike of guidance and ready reference in the diagnosis and treatment of disease

A further issue has taken place of *Nothnagel's Encyclopedia of Practical Medicine* the section dealing with typhoid and typhus fevers being issued from the pen of Dr H. CURSCHMANN Professor of Medicine Leipsic edited with additions by Professor WILLIAM OSLER (authorised translation from the German under the editorial supervision of ALFRED STENGEL, M D W B. Saunders and Co £1 1s). The excellence of the series of monographs issued under the editorship of Professor Nothnagel has been recognised by medical practitioners sufficiently familiar with German to read these works and the publication of an English edition will doubtless be most favourably received. A set of 10 volumes will be issued representing the most practical part of the work.

Several excellent examples of surgical and medical monographs have appeared during the past year One such book is *Diseases of the Stomach and their Surgical Treatment* by A W MAYO ROBSON and B G A MOYNIHAN (*Baillière* Tindall, and Cox, price 15s net) In 1900 Mr Mayo Robson delivered the Hunterian Lectures at the Royal College of Surgeons of England on the Surgery of the Stomach, and this has formed the foundation on which this book has been built though the two authors hold themselves jointly responsible for every statement in the book. There are many other matters dealt with in this volume besides the surgery of the stomach which are of eminently medical interest and importance

Another book that will prove of service to the medical profession is *A Text-book of Medical Jurisprudence Toxicology and Public Health* by Dr JOHN GLAISTER (E. and S Livingstone 15s). In this work the plan has been adopted of combining in a single text-book the subjects of medical jurisprudence toxicology and public health. We consider this method a good one both for practitioners and students. All three subjects imply relationships subsisting between the medical man and the State and at most of the qualifying examining boards the subjects are now conjoined for examining purposes Dr Glaister modestly remarks that on none of the subjects does the volume pretend to be exhaustive He has, however produced an excellent manual fully carrying out all that is claimed for it—that is to say that in its pages will be found a consideration of the most important problems in each of the departments of which it treats

We would also recommend to the notice of the student *Human Embryology and Morphology* by Dr ARTHUR KEITH (Edward Arnold 12s *6d*) No doubt can be entertained of the great value of a knowledge of embryology to the student of medicine It supplies to the anatomist a satisfactory key to many anomalies and peculiarities in the distribution of nerves and blood vessels and affords an explanation of many malformations, cysts, tumours and the like that the surgeon is called upon to treat. We venture to say that all the main facts of human embryology could be mastered by the student in the course of a month steady application to Dr Keith's treatise and we recommend the work as a trustworthy guide to human embryology The illustrations are numerous and if roughly drawn have one excellent feature—that the names of the several parts are printed at the side and well-defined lines are drawn from them to the objects specified.

A new edition has appeared of Dr DAWSON TURNER'S *Manual of Medical Electricity X Rays and Finsen Light* (Baillière Tindall, & Cox 7s *6d* net) The book has been revised and largely re-written and deals with subjects concerning which the well-equipped student ought to have knowledge

It will be gathered that the output of medical literature during the last 12 months has not been so large or important as usual, but we do not regard this fact with anxiety Some excellent books have been brought up to date, and with few exceptions our medical authors have felt the responsibility that lies upon them and have only written with great care from personal experience First-hand familiarity with the subject is the greatest essential to the manufacture of a good book—a fact which, we think, is becoming more widely recognised.

SESSION 1902–1903

◆

GENERAL COUNCIL OF MEDICAL EDUCATION AND REGISTRATION OF THE UNITED KINGDOM

Registration of Medical Students —The following are the General Medical Council's Regulations in reference to the registration of students in medicine —

Every medical student shall be registered in the manner prescribed by the General Medical Council. The registration of medical students shall be placed under the charge of the branch registrars Every person desirous of being registered as a medical student shall apply to the branch registrar of the division of the United Kingdom in which he is residing, and shall produce or forward to the branch registrar a certificate of his having passed a preliminary examination as required by the General Medical Council, and evidence that he has attained the age of 16 years and has commenced medical study The branch registrar shall enter the applicant's name and other particulars in the Students' Register, and shall give him a certificate of such registration Each of the branch registrars shall supply to the several qualifying bodies, medical schools, and hospitals in that part of the United Kingdom of which he is registrar, a sufficient number of blank forms of application for the registration of medical students The commencement of the course of professional study recognised by any of the qualifying bodies shall not be reckoned as dating earlier than fifteen days before the date of registration Applications for special exceptions are dealt with by the Students' Registration Committee, which reports all such cases to the Council

The Preliminary Examination in General Education, required to be passed previously to registration as a medical student, shall be as follows —

1. English language including grammar and composition. 2. Latin, including grammar, translation from unprescribed Latin books, and translation of English passages into Latin 3 Mathematics comprising (*a*) arithmetic (*b*) algebra, including easy quadratic equations, (c) geometry the subject matter of Euclid Books I., II, and III, with easy deductions. 4 One of the following subjects (*a*) Greek, (*b*) a modern language

In many cases the Council will not accept certificates of pass in Preliminary Examination in General Education unless the whole of the subjects included in the Preliminary Examination required by the Council for Registration of Students of Medicine have been *passed at the same time*

Professional Education —The course of professional study after registration shall occupy at least five years The Final examination in Medicine Surgery, and Midwifery must not be passed before the close of the fifth academic year of medical study

The following is a list of Examining Bodies whose examinations in general education are recognised by the General Medical Council as qualifying for registration as a medical or dental student the applicant producing satisfactory evidence that he has passed them —

I —UNIVERSITIES IN THE UNITED KINGDOM

University of Oxford —Junior Local Examinations Senior Local Examinations. Responsions Moderations Final Examination for a degree in Arts

University of Cambridge —Junior Local Examinations Senior Local Examinations Higher Local Examinations. Previous Examination. General Examination. Final Examination for a degree in Arts

University of Durham —Examination for Certificate of Proficiency Senior Local Examinations Final Examination for a degree in Arts

University of London —Matriculation Examination Final Examination for a degree in Arts or Science

Victoria University —Preliminary Examination Final Examination for a degree in Arts or Science

University of Birmingham —Matriculation Examination

University of Wales —Matriculation Examination. Final Examination for a degree in Arts or Science

University of Edinburgh —Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science for Medicine and Surgery Final Examination for a degree in Arts or Science

University of Aberdeen —Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery Final Examination for a degree in Arts or Science.

University of Glasgow —Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery Final Examination for a degree in Arts or Science

University of St Andrews —Preliminary Examination of the Joint Board of Examiners for Graduation in Arts or Science or Medicine and Surgery Final Examination for a degree in Arts or Science or for the diploma of L L A

University of Dublin —Public Entrance Examination Examination for the first, second, third, or fourth year in Arts. Final Examination for a degree in Arts

Royal University of Ireland —Matriculation Examination Final Examination for a degree in Arts or Science.

Oxford and Cambridge Schools Examination Board — Lower certificate (to include all the required subjects at one time) Higher certificate (to include the required subjects)

II —MEDICAL LICENSING BODIES

Royal Colleges of Physicians and Surgeons in Ireland — Preliminary Examination

III —EDUCATIONAL BODIES OTHER THAN UNIVERSITIES

College of Preceptors —Examination for a First Class Certificate, Preliminary Examination for Medical Students

Intermediate Education Board of Ireland —Middle Grade Examination, Senior Grade Examination

Educational Institute of Scotland — Preliminary Medical Examination

Scottish Education Department —Leaving Certificates in Lower and Higher Grades and in Honours

Central Welsh Board —Senior Certificate Examination

IV —INDIAN, COLONIAL, AND FOREIGN UNIVERSITIES AND COLLEGES

The Certificates from Indian, Colonial, and Foreign Universities and Colleges must contain evidence that the Examination has been conducted by or under the authority of the Body granting it, must include all the subjects required by the General Medical Council, and must state that all the subjects of Examination have been passed in at one time, copies of the form of the required Certificate are supplied by the Registrar of the Council for the purpose In the case of Natives of India or other Oriental countries whose vernacular is other than English an Examination in a Classical Oriental Language may be accepted instead of an Examination in Latin

H E Allen, LL.B, Registrar of the General Council and of the Branch Council for England, 299, Oxford-street, London, W —James Robertson, Registrar of the Branch Council for Scotland, 48 George-square, Edinburgh —S W Wilson, L R C P Irel, Registrar of the Branch Council for Ireland, 35 Dawson street, Dublin.

POWERS AND DUTIES OF THE GENERAL MEDICAL COUNCIL.

As there is apparently, even among members of the medical profession, a great amount of ignorance as to the powers and duties of the General Medical Council, we think it well to lay clearly before our readers what the General Medical Council is and also what it is not

Many of the false ideas on the subject are due to the use of the shortened title, "General Medical Council" The full title is, "General Council of Medical Education and Registration of the United Kingdom" This title is in accordance with the Medical Act of 1858, by which the General Medical Council was established to enable persons requiring medical aid to distinguish qualified from unqualified practitioners Registrars were to be appointed by the General Council and by the Branch Councils to keep registers of qualified persons Registrars were bound by Section XIV of the Act to keep their registers correctly, a duty which, mainly owing to the apathy of members of the medical profession, has not been adequately performed

It will thus be seen that the General Medical Council is primarily a body of gentlemen charged with looking after the education and registration of medical practitioners The sole penalty it can inflict is to strike a man's name off the Medical Register It is as well here to put down the advantages, such as they are, of being duly registered A duly registered practitioner may sue in the courts of law for the recovery of charges for medical attendance or advice, or surgical attendance or advice, or for the supply of medicine, or for the performance of any operation—provided that he is not debarred from suing by being a Fellow or a Member of any corporation which objects to its Fellows or Members so suing He may be exempted, if he so desire, from serving on juries from serving sundry corporate and parochial offices, and from serving in the Militia Only a registered practitioner can hold appointments in the navy, army and sundry Poor law and other institutions Only a registered person can sign a valid medical certificate Removal of the name from the Register debars a man from all the above mentioned privileges

Let us now consider what the General Medical Council is not. Unfavourable comparisons are often drawn between the General Medical Council and the Incorporated Law Society The two bodies are not in the very least upon the same footing The Incorporated Law Society is a society composed of such practitioners as apply for membership and are elected by the Council It is by statute the keeper of the roll of solicitors who have to pay a fee each year to obtain renewal of certificate to practise which certificate has then to be stamped by the Inland Revenue authorities on payment of the annual duty The society is also intrusted with the duty of inquiring into professional misconduct and reports thereon to the High Court which may or may not agree with the report. The offender is struck off the rolls by the court not by the society Only a minority of solicitors are members of the society The society has a charter and is governed by a council The somewhat analogous body in the medical profession is the British Medical Association which however has none of the legal powers possessed by the Incorporated Law Society

The General Medical Council is in no way a medical protection society or a medical defence union It is not a professional union or a guild charged with looking after the interests of the medical profession after the manner of the old trades guilds *excep in so far as it is* concerned with the education of medical students It has no powers over any *member of the medical profession* except to remove the name of any offending member from the roll of the *profession or Medical Register* It cannot take away any degree or diploma, or licence and even if a practi *tioner is struck off* the Medical Register there is nothing in the existing state of the law to prevent such practitioner continuing to practise provided that he does not use any name or title implying that he is registered. Practitioners *may be removed* from the Medical Register (1) if convicted of felony or misdemeanour in England or in Ireland or in *Scotland of* any crime or offence and (2) on being adjudged by the General Medical Council to have been guilty of infamous conduct in a professional respect. The words infamous conduct are certainly unfortunate for they cover such a comparatively trivial offence as advertising and such a truly infamous offence as that committed by a medical man who committed adultery with a married woman whom he was attending professionally

The General Medical Council is primarily a body charged with looking after medical education It is but little concerned with medical politics Inspection of the report of the sessions held in February and May 1902, shows that the time of the Council was almost entirely taken up with considering educational and registration matters the latter including the penal cases of removal from the Register A matter which perhaps comes under the head of medical politics was the case of Dr Robert Rendall, which was considered at the May session The Midwives Bill also received attention at the special session held in February The Council at present consists of 31 members, of whom as will be seen by the annexed list, all but 10 are representatives of some corporate body Five members are chosen by the Crown on the advice of the Privy Council and five others are elected by the members of the medical profession as Direct Representatives

President of the General Council.—Sir William Turner Members of the General Council —Dr Norman Moore chosen by the Royal College of Physicians of London Mr Thomas Bryant Royal College of Surgeons of England Sir Hugh Reeve Beevor Apothecaries Society of London Dr Joseph Frank Payne University of Oxford Dr Donald MacAlister University of Cambridge, Sir George Hare Philipson University of Durham Dr Philip Henry Pye-Smith University of London, Dr Alfred Harry Young Victoria University and Dr Bertram C A Windle, University of Birmingham. Sir John Batty Tuke chosen by the Royal College of Physicians of Edinburgh Dr Patrick Heron Watson Royal College of Surgeons of Edinburgh, Sir Hector Clare Cameron Faculty of Physicians and Surgeons of Glasgow Sir William Turner, University of Edinburgh Sir William Tennant Gairdner *University of Glasgow* D Davi White Finlay, University of Aberdeen and Dr John Yule Mackay, University *of St Andrews* Dr Lombe Atthill chosen by the Royal College of Physicians of Ireland Dr Charles Bent Ball Royal College *of Surgeons* in Ireland Mr Charles R C Tichborne Apothecaries Hall of Ireland Dr Edward Hallaran Bennett University *of Dublin* and Sir Christopher John Nixon, Royal University of Ireland Nominated by His Majesty with the advice of his Privy Council Mr Charles Sissmore Tomes Mr William Henry Power, Sir John Williams Dr David Caldwell McVail and Dr James Little Elected as Direct Representatives Mr George Brown Sir Victor Alexander Haden Horsley Dr William Bruce, Sir William Thomson and Mr George Jackson. Treasurers of the General Council Mr Thomas Bryant and Dr Philip Henry Pye Smith. Registrar of the General Council and of the Branch Council for England Mr Henry E. Allen LL.B B A. Registrar of the Branch Council for Scotland Mr James Robertson Registrar of the Branch Council for Ireland Mr S Wesley Wilson

---

REGULATIONS
OF THE
MEDICAL EXAMINING BODIES IN THE UNITED KINGDOM.

UNIVERSITY OF OXFORD

THERE are two degrees in Medicine B M and D M. and two degrees in Surgery B Ch and M Ch.

The B M and B Ch degrees are granted to those members of the University who have passed the Second Examination Graduates in Arts (B A. or M A) are alone eligible for these two degrees In order to obtain the degrees of B M and B Ch the following examinations must be passed —1. Preliminary subjects Mechanics and Physics Chemistry Animal Morphology and Botany 2. Professional (*a*) First Examination Subjects — Organic Chemistry unless the candidate has obtained a first or second class in Chemistry in the Natural Science School Human Physiology unless he has obtained a first or second class in Animal Physiology in the Natural Science School Human Anatomy, and Materia Medica with Pharmacy (*b*) Second Examination: Subjects — Medicine, Surgery Midwifery Pathology Forensic Medicine with Hygiene The approximate dates of the examinations are as follows —Preliminaries—Mechanic Physics and Chemistry, December and June Animal Morphology December and March Botany March and June Professional (First and Second B M) June and December

The First Examination for the degrees of B M and B.Ch. may be passed as soon as the Preliminary Scientific Examinations have been completed The subjects of this examination may be presented separately or in any combination or in any order provided Anatomy and Physiology be passed together

The Second Examination may be passed after the completion of the first but Pathology may be professed before with or after the remaining subjects Before admission to the Second Examination candidates must present Certificates of instruction in Infectious and Mental Diseases and of attendance on Labours, and of proficiency in the practice of Vaccination

The degree of D M is granted to Bachelors of Medicine of the University—(1) who took the degree of B.M previously to the end of Trinity Term, 1886, provided they have spent three years in the practice of Medicine after taking that degree, and have composed a dissertation on some medical subject approved by the Regius Professor of Medicine, before whom it must be read in public, (2) who took the degree of B M subsequently to the end of Trinity Term 1885 provided they have entered their thirty ninth term and have composed on some medical subject a dissertation which is approved by the professors in the Faculty of Medicine and examiners for the degree of B M whose subject is dealt with A book published within two years of the candidate s application for the degree may be substituted for a dissertation The Regius Professor may direct the dissertation to be read in publi The degree of M Ch is granted to Bachelors of Surgery of the University who have entered their twenty seventh term, who are members of the surgical staff of a recognised hospital, or have acted as Dresser or House Surgeon in such a hospital for six months, and who have passed an examination in Surgery, Surgical Anatomy, and Surgical Operations This examination is held annually, in June at the end of the Second B M. Examination

Scholarships, &c —Scholarships in some branch of Natural Science (Chemistry, Physics, Biology) of the average value of £80 per annum, tenable for four years and renewable under certain conditions for a fifth year, as well as Exhibitions of a less annual value, are awarded after competitive examination every year by some of the Colleges Notices of vacancy, &c , are published in the *University Gazette* In February there is competed for annually by those who, having obtained a first-class in any school (Moderations or final), or a Scholarship or Prize open to general competition in the University, have passed all the examinations for the degree of B M one Radcliffe Travelling Fellowship It is tenable for three years and is of the annual value of £200 The examination is partly scientific, partly medical The holder must travel abroad for the purpose of medical study A Rolleston Memorial Prize is awarded once in two years to members of the Universities of Oxford and Cambridge of not more than ten years' standing *for an original research in some* Biological *subject including Physiology or Pathology*

More detailed information may be obtained from the University Calendar , from the Examination Statutes, 1902, which contain the official schedules of the several subjects of examination in both Arts and Medicine , from the Student's Handbook to the University (all of which are published by the Clarendon Press) , from the Regius Professor of Medicine , and from the Professors in the several departments of medical science

The Lecturers for the various subjects are as follows — Regius Professor of Medicine Sir J S Burdon Sanderson, Bt , D M Pathological Histology and Practical Bacteriology The Reader in Pathology, J Ritchie, D M Edin Professor of Human Anatomy A Thomson, M A Waynflete Professor of Physiology F Gotch, M A., D Sc University Lecturer on Physiology J S Haldane, M A. Practical Physiology and Histology G Mann, D M Edin Physiological Chemistry Walter Ramsden, M A Lichfield Lecturer in Clinical Medicine W T Brooks, M A Lichfield Lecturer in Clinical Surgery H P Symonds, F R C S Edin Organic Chemistry in Relation to Medicine, &c , followed by Practical Work W W *Fisher, M.A* , (Aldrichian Demonstrator), and J E *Marsh*, M A. Lecturer in Materia Medica and Pharmacology W J Smith Jerome, B M Lond Linacre Professor of Comparative Anatomy, W F R Weldon, M A , D Sc Lee's Reader in Anatomy, J B Thompson, M A Elementary Animal Morphology (Practical) the Aldrichian Demonstrator E *Goodrich*, M A , and assistants Sherardian Professor of Botany S H Vines, M A. Waynflete Professor of Chemistry W Odling, M A Lees Reader in Chemistry A. G Vernon Harcourt, M.A Laboratory Instruction W W Fisher, M A J Watts, M A , V H Veley, M A , D Sc , and J E Marsh, M A Wykeham Professor of Physics, J S E Townsend, M A Professor of Experimental Philosophy R B Clifton, M A Instruction in Practical Physics R B Clifton, M A , J Walker, M A., P I Watkin, M.A , and W W Taylor, M A. Elementary Heat and Light Lees Reader in Physics R E Baynes, M A Elementary Mechanics F J Jervis Smith, M A.

UNIVERSITY OF CAMBRIDGE

The student must enter at one of the Colleges, or as a *non-collegiate student, and* keep nine terms (three years) by residence in the University He must pass the Previous Examination in Classics, Mathematics, &c., which may, and should if possible, be done before coming into residence in October, or he may obtain exemption through the Oxford and Cambridge Schools Examination Board or the Cambridge Senior Local Examinations He *may then* devote himself to medical study in the University, attending the hospital and the medical lectures, dissecting, &c Or he may, as nearly all students now do, proceed to take a degree in Arts, either continuing mathematical and classical study and passing the ordinary examinations for B A., or going out in one of the Honour Triposes The Natural Sciences Tripos is the most appropriate, as some of the subjects are practically the same as those for the first and second M B examinations.

For the degree of *Bachelor of Medicine (M B)* five years of medical study are required This time may be spent in Cambridge or at one of the recognised Schools of Medicine. The first three or four years are usually spent in Cambridge, the student remaining in the University till he has passed, say, the examination for the Natural Sciences *Tripos* and the first and second examinations for M B Cambridge being now a complete School of Medicine, all the requisite lectures and hospital practice may be attended here, and many students remain to attend lectures and hospital practice until they have passed the first part of *the third examination for* M.B The supply of subjects *for Dissection* is abundant and the laboratories for Pathology, Bacteriology, and Pharmacology are well equipped Addenbrooke's Hospital provides for the necessary clinical training

There are three examinations for M B The *first* includes Chemistry and other branches of Physics, and Elementary Biology These parts may be taken together or separately The *second* includes Human Anatomy and Physiology The *third* is divided into two parts—viz , (1) Pharmacology and General Pathology , (2) Principles and Practice of Surgery, Midwifery and Diseases peculiar to Women, Principles and Practice of Physic The examinations are partly in writing, partly oral, and partly practical, in the hospital, in the dissecting-room, and in the laboratories. *An Act has then to* be kept in the Public Schools, by the candidate reading an original dissertation composed by himself on some subject approved by the Regius Professor of Physic

As Operative and Clinical Surgery now form parts of the third M B examination candidates who have passed both parts of that examination are admitted to the registrable degree of *Bachelor of Surgery (B C)* without separate examination and without keeping an Act

The degree of *Doctor of Medicine* may be taken three years after that of M B or four years after that of M A. An Act has to be kept, consisting of an original Thesis sustained in the Public Schools, with *vivâ-voce* examination , and an extempore Essay has to be written on some subject relating to Physiology, Pathology, the Practice of Medicine, or State Medicine

For the degree of *Master of Surgery (M C)* the candidate must have passed all the examinations for B C , or if he is an M A. have obtained some other registrable qualification in surgery He is required *either* (1) to pass an examination in Surgical Anatomy and Surgical Operations, Pathology, and the Principles and Practice of Surgery, and to write an extempore Essay on a Surgical Subject , or (2) to submit to the Medical Board original contributions to the advancement of the Science or Art of Surgery Before he can be admitted to the examination two years at least must have elapsed from the time when he completed all required for the degree of B C Before submitting original contributions he must have been qualified at least three years

An abstract of the Regulations and Schedules of the range of the examinations in Chemistry, Physics, Biology, Pharmacology, and General Pathology may be obtained upon sending a stamped directed envelope to the Registrary, Cambridge

UNIVERSITY OF LONDON

The Matriculation Examination —Candidates must have passed the Matriculation examination. No exemption either from Matriculation or from subsequent examinations is allowed on account of medical degrees obtained at other Universities or of examinations of other medical examining bodies that may have been passed The examinations take place twice in each year—on the second Monday in January and the second Monday in June , and may be held not only at the University of London, but also, under special arrangement, in other parts of the United Kingdom or in the colonies Every candidate must, on or before April 25th for the June examination, and on or before Nov 25th for the January examination, apply to the Principal for a form of entry, which must be returned on or before May 1st or Dec 1st respectively, accompanied by a certificate showing that the candidate has completed his sixteenth year and by his fee for the examination A certificate from the Registrar General in London or from the superintendent registrar of the district, or a certified copy of the baptismal register, is required in every case in which it can possibly be obtained In other cases a declaration of the candidate's age, made before a magistrate by his parent or guardian, or by the candidate, if of full age, will be accepted. As candidates cannot be admitted after the list is closed, any candidate who may not have received a form of entry within a week after applying for it should communicate immediately with the Principal, stating the exact date of his application and the place where it was posted Every candidate must pay a fee of £2, and if he withdraws his name, or fails to present himself at the examination, or fails to pass it, the fee shall not be returned to him, except in the case of candidates who entered for a Matriculation examination before that of June, 1902 Candidates must show a competent knowledge of 1 Latin. 2. English Language History to the end of the seventeenth century with the Geography relating thereto 3 Mathematics (Elementary) 4 General Elementary Science 5 Any one of the following languages or sciences Greek French, German, Sanskrit, Arabic, Elementary Mechanics, Elementary Chemistry Elementary Sound, Heat and Light Elementary Magnetism and Electricity and Elementary Botany (No credit will be given for more than one of these subjects and candidates desiring to be examined in Sanskrit or Arabic must give two months notice to the Principal The examination in Botany is only held in the United Kingdom. Candidates in any one of the optional Branches of Science will find it an advantage to have obtained some elementary instruction in the practical use of apparatus.) A pass certificate signed by the Principal is delivered to each successful candidate after the report of the examiners shall have been approved by the Senate The first six candidates in the Honours Division, of not more than twenty years of age at the commencement of the examination, shall respectively receive an exhibition or a prize Any candidate obtaining a place in the Honours Division at the Matriculation examination in January shall be admissible to the Intermediate examination either in Arts or in Science in the following July

Provincial Examinations for Matriculation.—These examinations are appointed by the Senate from time to time upon the application of any city institution, or college desiring to be named as a local centre for one or more examinations, and are carried on simultaneously with the examinations in London under the supervision of sub-examiners also appointed by the Senate Candidates wishing to be examined at any provincial centre must give notice upon their forms of entry to the Principal of the University who will then make all necessary arrangements Besides the University fee a fee usually varying from £1 to £2 is charged by the local authorities, and must be paid *at the local centre* immediately before the commencement of the several examinations The answers of the candidates at the provincial examinations are reviewed by the examiners at the same time as the answers of the candidates examined in London, and a list of the candidates who have passed at each provincial examination is published at the time fixed by the regulations at the place where such examination has been held

Preliminary Scientific Examination.—Professional studies pursued before the whole of this examination has been passed will not count towards the course required for the M B degree. Candidates must have passed the Matriculation examination The examination takes place twice in each year once for Pass and Honours, commencing on the second Monday in July and once for Pass candidates only commencing on the third Monday in January Every candidate must apply by post-card to the External Registrar for a form of entry on or before May 24th for the July examination or on or before Dec 15th for the January examination which must be returned on or before June 1st and Dec 22nd respectively accompanied by the candidate's fee of £5 The subjects of the Preliminary Scientific Examination are divided into two sections: (1) Chemistry and Physics, and (2) General Biology Chemistry includes a written examination in Chemistry and a practical examination in Qualitative and Simple Volumetric Analysis Physics implies a knowledge of acoustics, heat magnetism, electricity and optics General Biology comprises a knowledge of the elements of zoological (vertebrate or invertebrate) and botanical morphology physiology and embryology Candidates shall be allowed to enter for the whole examination or for either section Candidates who present themselves for the two sections together shall be credited with either section in which they may have passed, although they may have failed to pass in the other but no such candidate shall be placed in the Honours List Candidates must bear in mind that the standard of attainment for the Honours examination is much higher than that for the Pass examination, and they should therefore exercise due caution in making their choice to which they will be required to adhere. Candidates for Honours in Botany and Zoology must take the Pass examination in General Biology, in other respects no candidate may take both the Pass and the Honours papers in the same subject The fee of £5 covers the whole of the examination, whether taken altogether or in sections

Provincial Examinations for the Preliminary Scientific Examination.—The Pass examination (except the practical examinations) may be held not only at the University of London but also under special arrangements in other parts of the United Kingdom All Honours papers, some of which under former arrangements used to be given out at the provincial centres must now be taken only at the University of London

Bachelor of Medicine—Every candidate for the degree of Bachelor of Medicine will be required—1. To have passed the Matriculation examination in this University not less than five years previously 2 To have passed the Preliminary Scientific examination not less than four years previously 3. To have been engaged in his professional studies during five years subsequently to Matriculation and four years subsequently to passing the Preliminary Scientific examination at one or more of the medical institutions or schools recognised by this University one year at least of the four being spent in one or more of the recognised institutions or schools in the United Kingdom. 4 To pass two examinations in Medicine.

Intermediate Examination—The Intermediate examination in Medicine takes place twice in each year—once for Pass and Honours commencing on the first Monday in July and once for Pass candidates only commencing on the third Monday in January The subjects of the examination are Anatomy Physiology and Histology Organic Chemistry Materia Medica, and Pharmaceutical Chemistry The standard of attainment required for Honours is much higher than for a Pass No candidate shall be admitted to this examination unless he have passed the Preliminary Scientific examination at least two years previously and have produced certificates to the following effect—1. Of having completed his nineteenth year 2 Of having subsequently to having passed the Preliminary Scientific examination, been a student during two years at one or more of the medical institutions or schools recognised by this University and of having attended a course of lectures on each of three of the subjects in the following list Descriptive and Surgical Anatomy Physiology and Histology Pathological Anatomy Materia Medica and Pharmacy General Pathology General Therapeutics, Forensic Medicine Hygiene, Obstetric Medicine and Diseases Peculiar to Women and Infants, Surgery Medicine 3 Of having subsequently to having passed the Preliminary Scientific examination, dissected during two sessions 4 Of having subsequently to having passed the Preliminary Scientific examination, attended a course of Practical Chemistry comprehending practical exercises in conducting the more important processes of general and pharmaceutical chemistry in applying tests for discovering the adulteration of articles of the *Materia Medica* and the presence and nature of poisons, and in the examination of mineral waters animal secretions urinary deposits, calculi, &c. 5. Of having attended to Practical Pharmacy and of having acquired a practical knowledge of the preparation of medicines These certificates (as is the case also with all the certificates hereinafter mentioned) must be transmitted to the Registrar at least four weeks before the commencement of the examination Fee for this examination £5

M B Examination.—The M B examination takes place twice in each year—once for Pass and Honours, commencing on the last Monday in October and once for Pass candidates only commencing on the first Monday in May The subjects of the examination are *General Pathology* General Therapeutics, Hygiene, Surgery Medicine, Obstetric Medicine, and Forensic Medicine. No candidate will be admitted to this examination within twenty-one months of the time of his passing the Intermediate examination unless he be a registered medical practitioner of not less than three years standing in which case he must produce certificates of having gone through the required course of training at any time previously Every candidate must produce certificates —1. Of having passed the Intermediate examination 2 Of having attended a course of lectures on each of two of the subjects enumerated above in the regulations for that examination for which the candidate had not on that occasion presented certificates 3 Of having conducted at least twenty labours Certificates on this subject will be received from any legally qualified practitioner in Medicine 4 Of having attended the Surgical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Surgery 5 Of having attended the Medical Practice of a recognised hospital or hospitals during two years, with clinical instruction and lectures on Clinical Medicine, including Infectious Diseases and Lunacy 6 Of having, after having attended Surgical and Medical Hospital Practice for at least twelve months subsequently to passing the Intermediate examination in Medicine, attended to Practical Medicine, Surgery, or Obstetric Medicine, with special charge of patients, in a hospital, infirmary, dispensary, or parochial union during six months, such attendance not to be counted as part of either the Surgical or the Medical Hospital Practice prescribed in Clauses 4 and 5 7 Of having acquired proficiency in Vaccination Certificates on this subject will be received only from the authorised vaccinators appointed by the Privy Council The fee for this examination is £5

Bachelor of Surgery —The examination for the degree of Bachelor of Surgery takes place once in each year and commences on the Tuesday following the first Monday in December Candidates must produce certificates to the following effect —1 Of having passed the examination for the degree of Bachelor of Medicine in this University 2 Of having attended a course of instruction in Operative Surgery and of having operated on the dead subject The subjects of the examination are Surgery and Pathology and Surgical Anatomy Fee £5

Master in Surgery —The examination for the degree of Master in Surgery takes place once in each year and commences on the first Monday in December Candidates must produce certificates to the following effect —1 Of having taken the degree of Bachelor of Surgery in this University 2 Of having attended, subsequently to having taken the degree of Bachelor of Surgery in this University (*a*) to Clinical or Practical Surgery during two years in a hospital or medical institution recognised by this University, or (*b*) to Clinical or Practical Surgery during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of his profession , or (*c*) of having been engaged during five years in the practice of his profession, either before or after taking the degree of Bachelor of Surgery in this University One year of attendance on Clinical or Practical Surgery, or two years of practice, will be dispensed with in the case of those candidates who at the B S examination have been placed in the first division 3 Of moral character, signed by two persons of respectability The examination is conducted by means of printed papers and *vivâ-voce* interrogation, and the subjects are Mental Physiology (especially in its relations to mental disorder) and Surgery Any candidate for the degree of M S may transmit to the External Registrar, not later than Oct. 1st, a printed dissertation, thesis, or commentary, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Surgical Science , and if the thesis be approved by the examiners the candidate will be exempt from the written examination in Surgery The fee is £5

Doctor of Medicine —The examination for this degree takes place once in each year and commences on the first Monday in December Candidates may present themselves for examination either in Medicine or State Medicine Those presenting themselves for the M D examination in Medicine must produce certificates to the following effect —1 Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this University (*a*) to Clinical or Practical Medicine during two years in a hospital or medical institution recognised by this University; (*b*) or to Clinical or Practical Medicine during one year in a hospital or medical institution recognised by this University, and of having been engaged during three years in the practice of their profession , (*c*) or of having been engaged during five years in the practice of their profession, either before or after taking the degree of Bachelor of Medicine in this University 2 Of moral character, signed by two persons of respectability. One year of attendance on Clinical or Practical Medicine, or two years of practice, will be dispensed with in the case of those candidates who at the M B Examination have been placed in the First Division Candidates presenting themselves for the M D examination in State Medicine must produce certificates to the following effect —1 Of having attended, subsequently to having taken the degree of Bachelor of Medicine in this university (*a*) to State Medicine during two years, including six months' practical instruction in a laboratory and six months' outdoor sanitary work, (*b*) or to State Medicine during one year, and of having held for a period of two years the position of medical officer of health in any sanitary district, (*c*) or of having held for a period of three years the position of medical officer of health in any sanitary district 2 Of moral character One year of attendance on State Medicine or one year of holding the position of medical officer of health will be dispensed with in the case of those candidates who at the M B examination have been placed in the First Division The examination is conducted by means of printed papers and *vivâ voce* interrogation, and the subjects are Medicine (or State Medicine) and Mental Physiology (especially in its relation to mental disorder) Any candidate for the degree of M D may transmit to the External Registrar, not later than Oct 1st, a printed thesis, written in view of candidature, or published within two academical years immediately preceding, treating scientifically some special department of Medical Science , and if the thesis be approved by the examiners the candidate will be exempt from the written examination in Medicine (or State Medicine) The fee is £5

UNIVERSITY OF DURHAM

One Diploma and six degrees are conferred — viz , the Diploma in Public Health and the degrees of Bachelor in Medicine, Bachelor in Surgery, Master in Surgery, Doctor in Medicine, Bachelor in Hygiene, and Doctor in Hygiene These degrees are open both to Men and Women

For the degree of *Bachelor in Medicine* (*M B*) there are four professional examinations

The subjects of the First Examination are—Elementary Anatomy and Elementary Biology, Chemistry, and Physics

The subjects of the Second Examination are—Anatomy, Physiology, Materia Medica, Therapeutics, Pharmacology, Pharmacy

The subjects of the Third Examination are—Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology

The subjects of the Fourth Examination are—Medicine, Clinical Medicine and Psychological Medicine, Surgery and Clinical Surgery, Midwifery and Diseases of Women and Children

N B —It is required that at least one of the five years of professional education shall be spent in attendance at the University College of Medicine, Newcastle upon-Tyne Candidates who have passed the First and Second Examinations of the University will be exempt from First and Second Examinations of the Conjoint Board

For the degree of *Bachelor in Surgery* (*B S*) every candidate must have passed the examination for the degree of Bachelor in Medicine of the University of Durham and must have attended one course of lectures on Operative Surgery and one course on Regional Anatomy Candidates will be required to perform operations on the dead body and to give proof of practical knowledge of the use of surgical instruments and appliances

For the degree of *Master in Surgery* (*M S*) candidates must not be less than twenty four years of age and must satisfy the University as to their knowledge of Greek. In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M B degree they must present themselves at Durham for examination in it, at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M S They must also have obtained the degree of Bachelor in Surgery of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Surgery, in attendance on the practice of a recognised hospital, or in the naval or military services, or in medical or surgical practice

The subjects of examination are —Principles and Practice of Surgery, Surgical Pathology Surgical Anatomy Surgical Operations, Clinical Surgery

For the degree of *Doctor in Medicine (M D)* candidates must be not less than twenty four years of age and must satisfy the University as to their knowledge of Greek In case they shall not have passed in this subject at the Preliminary Examination in Arts for the M B degree they must present themselves at Durham for examination in it at one of the ordinary examinations held for this purpose before they can proceed to the higher degree of M D They must also have obtained the degree of Bachelor in Medicine of the University of Durham and must have been engaged for at least two years subsequently to the date of acquirement of the degree of Bachelor in Medicine in attendance on the practice of a recognised hospital, or in the military or naval services, or in medical and surgical practice. Each candidate must prepare an essay, which must be typewritten based on original research or observation on some medical subject selected by himself, and approved of by the Professor of Medicine and must pass an examination thereon, and must be prepared to answer questions on the other subjects of his curriculum so far as they are related to the subject of the essay

The University of Durham has instituted a special examination whereby the degree of Doctor of Medicine may be obtained without residence. Candidates shall not be under 40 years of age and shall have been in active practice for 15 years as registered medical practitioners They shall produce certificates of moral character from three registered members of the medical profession, and if they have not, passed an examination in Arts previously to the Professional Examination in virtue of which they have been placed on the Register they shall be required to pass in Classics and Mathematics Candidates who have passed an examination in Arts previously to being placed on the Register are required to pass an examination in Latin They will be examined in the Principles and Practice of Medicine including Psychological Medicine, Hygiene, and Therapeutics, the Principles and Practice of Surgery Midwifery, and Diseases of Women and Children, Pathology (Medical and Surgical) Anatomy (Medical and Surgical) Medical Jurisprudence, and Toxicology The fee will be 50 guineas of which 20 guineas will be retained if the candidate fails to satisfy the examiners

Candidates for any of the above degrees must give at least 28 days notice to Professor Howden Secretary College of Medicine, Newcastle-on Tyne

VICTORIA UNIVERSITY (MANCHESTER).

Colleges of the University Owens College, Manchester, University College, Liverpool, and Yorkshire College Leeds

Matriculation, which consists in signing the University Register must precede entry upon any course of study in a College of the University if that course is to be counted towards the required minimum of attendance for a degree Those only can matriculate who are registered students of a College of the University

Four degrees in Medicine and Surgery are conferred by the Victoria University—viz. Bachelor of Medicine and Bachelor of Surgery (M B and Ch B.) Doctor of Medicine (M D) and Master of Surgery (Ch M)

All candidates for degrees in Medicine and Surgery are required to pass an examination called the Preliminary Examination (Faculty of Medicine) or to have passed such other examination as may be recognised by the University for this purpose.[1]

Degrees of Bachelor of Medicine and Bachelor of Surgery —Before admission to the degree of M B or Ch.B candidates are required to present certificates that they will have attained the age of 21 years on the day of graduation and that they have pursued the courses of study required by the University Regulations during a period of not less than five years subsequently to the date of their registration by the General Medical Council, two of such years having been passed in a College of the University and one year at least having been passed in a College of the University subsequently to the date of passing the First M B Examination All candidates for the degrees of Bachelor of Medicine and Bachelor of Surgery are required to satisfy the examiners in the several subjects of the following examinations the First Examination, the Second Examination, and the Final Examination

The First Examination —The subjects of examination are as follows —(1) Chemistry, (2) Elementary Biology, (3) Physics Candidates must have attended during at least one year courses both of lectures and of laboratory work in each of the above-named subjects The Examination is divided into two parts Part 1, Physics and Chemistry, Part 2, Biology, and the candidates may pass in these parts separately

The Second Examination —The subjects of examination are as follows —A (1) Anatomy, (2) Physiology including Physiological Chemistry and Histology, B: (3) Materia Medica and Pharmacy Candidates may pass in A and B separately

The Final Examination —The subjects of examination are as follows —(1) Pharmacology and Therapeutics (2) General Pathology and Morbid Anatomy (3) Forensic Medicine and Toxicology and Public Health (4) Obstetrics and Diseases of Women. (5) Surgery Systematic, Clinical and Practical. (6) Medicine Systematic and Clinical, including Mental Diseases and Diseases of Children.

Candidates may either present themselves in all the six subjects of examination on the same occasion or may pass the examination in two parts, the first part consisting of *two* or *three* of the subjects (1) (2) and (3) the second part of the remaining subjects

Candidates who fail to satisfy the examiners in the first part must either present themselves again in the subjects as selected or in all the three subjects of the First part or in all the six subjects of examination

Candidates for the first part of the examination must have completed the *fourth winter* of medical study

Candidates for the second part of the examination, or for the whole examination, must have completed the fifth year of medical study

Degree of Doctor of Medicine —Candidates are not eligible for the degree of Doctor of Medicine unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees. Candidates for the degree of Doctor of Medicine are required to present a printed dissertation embodying the results of personal observations or original research, either in some department of medicine or of some science directly relative to medicine No candidate will be admitted to the degree unless his dissertation shall have been recommended by the General Board of Studies to the Council for acceptance Candidates may be examined on any subject connected with their dissertations.

Degree of Master of Surgery —Candidates are not eligible for the degree of Master of Surgery unless they have previously received the degrees of Bachelor of Medicine and Bachelor of Surgery and at least one year has elapsed since they passed the examination for those degrees The subjects of examination are as follows (1) Surgical Anatomy (2) Surgery (3) Operative Surgery (4) Clinical Surgery (5) Ophthalmology, and (6) Pathology and Bacteriology

Communications should be addressed to the Registrar Victoria University Manchester

UNIVERSITY OF BIRMINGHAM

The University of Birmingham grants the degrees of M B, B.Ch M D, M Ch and also a B Sc, and a [illegible] diploma in Public Health In order to obtain any of these degrees it is necessary that a student shall have passed at least the first four years of his curriculum in attendance upon the classes of the University

---

[1] The examinations at present recognised are:—1 Graduation in this or some other university of the United Kingdom provided that Latin has formed part of one of the Degree Examinations 2. London Matriculation. 3 Higher Certificate of the Oxford and Cambridge Schools Examination Board. (Certificates must show that the candidate has satisfied the Examiners in Latin, Elementary and Additional Mathematics, English or History and in either Greek French or German. The Mechanical Division of Natural Philosophy will satisfy the requirements in Mechanics.) 4. Senior Oxford Locals (Honours). (Certificates must show that the candidate has satisfied the Examiners in Latin, Pure Mathematics English Essay English History and in either Greek, French German, or Spanish Applied Mathematics (Section D) or Mechanics and Hydrostatics (Section E) will satisfy the requirements in Mechanics) 5. Senior Cambridge Locals (Honours). (Certificates must show that the candidate has satisfied the Examiners in Latin, Euclid, and Algebra, English Composition, and English History and in either Greek French German, or Spanish Applied Mathematics (Section H) or Statics Dynamics, and Hydrostatics (Section K) will satisfy the requirements in Mechanics. Provided that the subjects included in each of the above examinations shall include all the subjects required by the General Medical Council If Mechanics has not been included among the subjects of examination so accepted [illegible] in that subject must be passed before the [illegible] the First M B Examination The Board of Studies has discretionary power to accept other [illegible]

Degrees of Bachelor of Medicine and Bachelor of Surgery —The student must have passed either the Matriculation Examination of the University or one of the following examinations For the present the University will recognise any one of the following examinations, in lieu of its own Matriculation, in the case of medical students provided always that such examination shall have included the subjects of English, Latin, Mathematics, and any one of the following Greek, French German or any other modern foreign language, and that all the subjects have been passed at one examination (*a*) the previous examination of the University of Cambridge, (*b*) responsions of the University of Oxford, (*c*) the Preliminary or Matriculation Examination of any recognised University, (*d*) the (Higher) Certificate of the Oxford and Cambridge Examinations Board, (*e*) the Oxford or Cambridge Junior Local Examinations, with First or Second Class Honours, or with Distinctions in two subjects, which may be either languages or mathematics, (*f*) the Oxford or Cambridge Senior Local Examination, (*g*) the College of Preceptors' Examination for First Class Certificate A Matriculation Examination will be held on Sept 15th, 1902, and succeeding days First Examination — Chemistry and Physics Second Examination — Anatomy, Comparative Anatomy, and Physiology Third Examination —Materia Medica and Pharmacy Fourth Examination (at the end of the fourth year) —Pharmacology, Pathology Forensic *Medicine*, *Toxicology*, and Public Health Two years' hospital work must have been accomplished Final Examination —Medicine, Surgery, Midwifery, Gynæcology, Mental Diseases and Ophthalmology Attendance at a general hospital for a year after the passing of the fourth examination will be required, also attendance at a fever hospital and lunatic asylum Vaccination instruction must be taken out and courses of Ophthalmology, Medical and Surgical Anatomy and Operative Surgery,

Degrees of Doctor of Medicine and Master of Surgery —Candidates for either of these degrees will be required either (*a*) to present a thesis embodying original observations in some subject embraced in the medical curriculum and approved by a board of medical examiners to whom the thesis will subsequently be submitted, on the report of which board the degree will be awarded or withheld (the candidate may be examined on the subject which he has chosen for his thesis and the examiners may require to see the notes of original observations on which the thesis is based), or (*b*) to pass a general examination (written and practical) in Medicine or Surgery, according to the degree desired, and, in addition to show special proficiency in any one of the following subjects to be chosen by the candidate For the degree of M D (*a*) Infectious Diseases (*b*) Diseases of the Chest (*c*) Diseases of the Abdomen, (*d*) Nervous Diseases, (*e*) Diseases of Children, (*f*) Midwifery, (*g*) Pathology, (*h*) Bacteriology, (*i*) Medical Jurisprudence and Toxicology, (*j*) Public Health (*l*) Mental Diseases or (*l*) Diseases of the Skin For the degree of M Ch (*a*) Regional Surgery (*b*) Gynæcology, (*c*) Ophthalmology, or (*d*) Diseases of the Ear, Nose and Throat

Degree in Public Health —For the regulations for this degree and for the diploma in the same subject see p 621

Fees —Matriculation, £2, First Examination, £5, Second Examination, £5 Third Examination, £1, Fourth Examination, £3, Final Examination, £5

UNIVERSITY OF EDINBURGH

Four Degrees in Medicine and Surgery are conferred by the University of Edinburgh—viz, Bachelor of Medicine (M B), Bachelor of Surgery (Ch B), Doctor of Medicine (M D) and Master of Surgery (Ch M) The degree of Bachelor of Surgery cannot be conferred on any person who does not at the same time obtain the degree of Bachelor of Medicine, and similarly the degree of Bachelor of Medicine is not conferred on any person who does not at the same time obtain the degree of Bachelor of Surgery

A special University certificate in Diseases of Tropical Climates is also granted to qualified medical practitioners and others specially interested after approved attendance on the courses of instruction in Tropical Diseases and Practical Bacteriology, including the Micro organisms of Tropical Diseases.

Before commencing his medical studies each student must pass a preliminary examination in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek or French or German Provided always that, in the case of a candidate whose native language is not English, an examination in the native language of the candidate may be substituted for one in either French or German, and an examination in any other classical language for one in Latin or Greek.

No one is admitted to the degrees of Bachelor of Medicine and Bachelor of Surgery who has not been engaged in Medical and Surgical study for five years No course of lectures will be allowed to qualify unless the lecturer certifies that it has embraced at least 100 lectures, or 50 lectures, as may be required by the regulations, and that the student has also duly performed the work of the class

Candidates for the degrees of M B and Ch B must have attended for at least three academic years the medical and surgical practice either of the Royal Infirmary, Edinburgh, or of a general hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons They must have attended Clinical Surgery during a course or courses extending over not less than nine months These courses may be conducted by the professor of clinical surgery, or by professors or lecturers appointed for the purpose by the University Court, or by the ordinary surgeons of the Royal Infirmary, Edinburgh, or of a general hospital defined and recognised as hereinbefore provided, and shall consist of regular instruction at the bedside, along with clinical lectures A similar course of clinical medicine during a course or courses extending over not less than nine months is required The candidate must have attended a course of instruction in Mental Diseases given by the University Lecturer, or by a recognised Teacher, consisting of not less than six Class room meetings for lectures and demonstrations and ten meetings in the Wards of a recognised Asylum for the insane The candidate must have attended a course of 25 meetings on Practical Pharmacy in a university or recognised school of medicine, or have dispensed drugs for a period of three months in a hospital or dispensary, or in an establishment recognised by the Pharmaceutical Society The candidate must have attended for at least six months, by apprenticeship or otherwise, the out-practice of a hospital, or the practice of a dispensary, or of a physician or surgeon, or of a member of the London or Dublin Society of Apothecaries He must have acted as clerk in the medical wards and dresser in the surgical wards of a public hospital for a period of six months in each case, and must also have availed himself, to such an extent as may be required by the Senatus, with the approval of the University Court, of opportunities of studying at a hospital or dispensary *Post-mortem Examinations, Fevers, Diseases of* the Eye, Operative Surgery, and one of the three following, viz —Diseases of Children, and Diseases of the Larynx, Ear, and Nose, and Diseases of the Skin, or such other special departments as may from time to time be determined The candidate must have attended, under the superintendence of a registered medical practitioner twelve cases of labour, or such additional number as the Senatus, with the sanction of the University Court, may from time to time determine; or have attended for three months the practice of a lying-in hospital, or of the maternity department of a general hospital or other public charitable institution, and have conducted personally six or such an additional number of cases of labour as the Senatus, with the approval of the University Court, may from time to time determine The candidate must have been properly instructed in Vaccination at a public vaccination station, by a public vaccinator, authorised by the proper Government authority to grant certificates of proficiency in vaccination

Next, with respect to the places and institutions at which the studies of the candidate may be prosecuted, the following regulations have effect —Two of the five years of medical study must be spent in the University of Edinburgh The remaining three years may be spent in any University of the United Kingdom, or in any Indian, Colonial, or Foreign university recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court Of the subjects of study, 16 in number—viz, Anatomy Practical Anatomy, Chemistry, Practical Chemistry, Materia Medica, Physiology, Practical Physiology Practice of Medicine, Surgery, Midwifery and Diseases of Women, Pathology, Practical Pathology, Physics, Botany, Zoology, Medical Jurisprudence, and Public Health—not less than eight must be taken in the University of Edinburgh or in some other university of the United Kingdom, or in some Foreign or Colonial university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court, or in a college incorporated with, or affiliated to a university entitled to confer the degree of Doctor of Medicine, recognised for the purpose by the University Court.

Women are admitted to graduation in medicine under practically the same conditions as men, excepting that until provision is made in the University for instruction of women in all subjects of the medical curriculum the regulations as to places of study contained in the foregoing paragraph do not apply to them. The Medical College for Women, 30, Chambers-street, Edinburgh, has been recognised as a medical school whose courses of instruction qualify for graduation.

Each candidate is examined both in writing and orally and clinically where the nature of the subject admits:—First, in Chemistry, Zoology, Botany, and Physics; second, in Anatomy, Physiology, Materia Medica and Therapeutics; third, in Pathology; and fourth, in Surgery, Medicine, Midwifery, Forensic Medicine, and Public Health, and clinically in Medicine and Surgery in a hospital. The examinations are conducted, as far as possible, by demonstrations of objects placed before the candidates. Candidates who profess themselves ready to submit to an examination in the first division of these subjects may be admitted to examination therein at the first period of examination after they have completed their attendance on the necessary classes. Candidates who have passed their examination in the first division of these subjects may be admitted to examination in the second division at the end of their third winter session. Candidates who have passed their examinations in the subjects comprised in the first and second divisions may be admitted to examination in the third division at the end of the fourth winter session. Candidates who have passed their examinations in the subjects comprised in the first, second, and third divisions may be admitted to examination in the fourth or final division when they have completed the fifth year of study.

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery is £23 2*s*., and the proportion of this sum to be paid by a candidate at each division of the examination shall be as follows—viz.: For the First Division of the Examination (Botany, Zoology, Physics, and Chemistry), £6 6*s*.; for the Second Division (Anatomy, Physiology, and Materia Medica and Therapeutics), £6 6*s*.; for the Third Division (Pathology), £4 4*s*.; and for the Final Division (Surgery and Clinical Surgery, Medicine and Clinical Medicine, Midwifery and Forensic Medicine and Public Health), £6 6*s*. The fee to be paid for the degree of Doctor of Medicine is £10 10*s*., and the fee to be paid for the degree of Master of Surgery is £10 10*s*.

UNIVERSITY OF GLASGOW.

The University of Glasgow is both a teaching and a degree-granting body, but admits to graduation only candidates whose preliminary examination and course of study conform to its own regulations. Within certain limits instruction given by recognised medical schools and teachers may be accepted, but eight of the subjects other than clinical must be taken in this or some other recognised university entitled to confer the degree of M.D., and at least two years of the course must be taken in Glasgow University. Under the new regulations four degrees, open both to men and women, are conferred: M.B. and Ch.B. (always conjointly), M.D., and Ch.M. A Preliminary Examination must be passed in (1) English, (2) Latin, (3) Elementary Mathematics, and (4) Greek, or French, or German, with possible options to students whose native language is not English in the case of the fourth subject. Candidates taking the University preliminary examination are not obliged to pass in all the four subjects at one examination, but must do so at not more than two occasions. For the degrees of M.B. and Ch.B. a curriculum of five years is required, in each of the first four of which the student must attend at least two five months courses, or alternatively one five months course and two courses of two and a half months. The minimum of attendance in the first four years includes five months courses in the following subjects:—Anatomy, Practical Anatomy (two courses), Chemistry, Materia Medica and Therapeutics, Physiology, Practice of Medicine, Surgery, Midwifery and Diseases of Women and Infants, and Pathology; and courses of two and a half months in the following:—Practical Chemistry, Physics, Botany, Zoology, Practical Physiology, Practical Pathology, Medical Jurisprudence and Public Health. Candidates must attend at least three years the Medical and Surgical Practice of a recognised hospital accommodating at least 80 patients and having a distinct staff of physicians and surgeons. At least nine months hospital attendance is required on both Clinical Surgery and Clinical Medicine, and the student must have acted as clerk in medical and dresser in surgical wards, and must have had six months' out-door practice; he must also have attended a course of Mental Diseases and of Practical Pharmacy (25 meetings), must have been properly instructed in Vaccination at a public vaccination station, and must have attended at least 12 cases of labour, or three months of the practice of a Lying-in Hospital, six cases being personally conducted. The University also requires further study in Post-Mortem Examinations, Fevers, and Ophthalmology, and recommends study in other special subjects. If a candidate has completed in a University of the United Kingdom a course of study and passed an examination in Botany, Zoology, Physics, or Chemistry qualifying for a degree in Science or in Arts, he is held to have passed the examinations in such subject or subjects.

There are four Professional Examinations, the first comprising Botany, Zoology, Physics, and Chemistry, to be taken after the completion of the included courses (candidates being at liberty to take two subjects at a time); the second comprising Anatomy, Physiology, and Materia Medica and Therapeutics, to be taken at the end of the third winter session; the third comprising Pathology, Medical Jurisprudence and Public Health, to be taken at the end of the fourth winter session; and the fourth or final, comprising Surgery, Clinical Surgery, Practice of Medicine, Clinical Medicine, and Midwifery, to be taken on completion of the fifth year of study.

The degrees of M.D. (Doctor of Medicine) and Ch.M. (Master of Surgery) are higher degrees in Medicine and Surgery respectively, and candidates (not under 24 years of age) who have previously obtained the double bachelorship may be admitted to either M.D. or Ch.M. on completing the after course prescribed, including an examination in Clinical Medicine for M.D., and an examination in Surgical Anatomy, operations on the dead body, and Clinical Surgery for Ch.M.

Fees.—The fees for M.B. and Ch.B. are £23 2*s*. The class fee in each subject of the curriculum for M.B. and Ch.B. is £3 3*s*., and the present fees for hospital attendance are £21. The fee for M.D. is £10 10*s*. (stamp duty being now abolished), and for Ch.M. £10 10*s*.

During last academic year there were 602 men and 71 women attending University courses in the Faculty of Medicine—a total of 673. The great majority of the students take their hospital course at the Western Infirmary, where clinical instruction is given by professors of the University and other physicians and surgeons. Clinical instruction on Fevers is given at Ruchill and Belvidere Hospitals, while special courses largely of a practical nature and embracing work in Hospital or Asylum wards, are conducted by University Lecturers on the Eye, the Ear, the Throat and Nose, and Insanity. Queen Margaret College, hitherto conducted as a separate institution for the higher education of women, has now been made over to the University, and in it medical classes for women are conducted under University professors and other lecturers appointed by the University Court, whilst for clinical instruction female students are admitted to the Royal Infirmary. Since 1894, the year in which the University first conferred degrees on women, [illegible]0 women have graduated in Medicine.

Bursaries and Prizes to the annual amount of about £[illegible] are appropriated to medical students, and Scholarships and Fellowships to the annual amount of about £1[illegible] may be held by medical students who have gone through the Arts course.

UNIVERSITY OF ABERDEEN.

The curricula for the several degrees conferred are exactly the same as in the Universities of Edinburgh and Glasgow.

Professional Examinations are held twice in each year—

namely, in March and July, directly after the close of the winter and summer sessions

The fees for graduation are the same as in the University of Edinburgh Matriculation fee, including all dues, for the winter and summer sessions, £1 1*s*, summer session alone, 10*s* 6*d*

Besides the Royal Infirmary, students have the opportunity of attending the following institutions General Fever Hospital, Sick Children's Hospital, General Dispensary, and Lying in and Vaccine Institutions daily, Royal Lunatic Asylum, Eye Institution, in which is given clinical instruction on Diseases of the Eye, and on the application of the Ophthalmoscope for their diagnosis

A diploma in Public Health is granted by the University to graduates in Medicine of a University in the United Kingdom, after a special examination The diploma can be entered on the Register of the General Medical Council

Application for further information should be addressed to the Secretary of the Medical Faculty

UNIVERSITY OF ST ANDREWS (UNITED COLLEGE, ST ANDREWS AND UNIVERSITY COLLEGE, DUNDEE)

The following are extracts from the Regulations for Degrees in Medicine contained in Ordinance No 45 (St Andrews, No 4) of the Commissioners under the Universities (Scotland) Act, 1889 These regulations came into force on April 19th, 1897 Four Degrees in Medicine and Surgery shall be conferred by the University of St Andrews—viz, Bachelor of Medicine (M B), Bachelor of Surgery (Ch B), Doctor of Medicine (M D) and Master of Surgery (Ch M) The degrees of M B and Ch B shall always be conjoined Before commencing his medical studies each student shall pass a Preliminary Examination in, (*a*) English, (*b*) Latin, (*c*) Elementary Mathematics, and (*d*) one of the following optional subjects —(*α*) Greek, (*β*) French, (*γ*) German, (*δ*) Italian, (*ε*) any other Modern Language, (*ζ*) Logic A degree in Arts or in Science in any of the universities of the United Kingdom and in some colonial or foreign universities shall exempt from the Preliminary Examination The Preliminary Examination for graduation in Medicine and Surgery, Arts or Science, of the University of St Andrews is accepted as equivalent to the Registration Examination required by the General Medical Council (the certificate to include the required subjects) Also the Final Examination for a degree in Arts or Science and the final examination for the Diploma of L L A

Candidates for the degree of Bachelor of Medicine and Bachelor of Surgery must have been engaged in medical study for at least five years In each of the first four years the candidate must have attended at least two courses of instruction in one or more of the subjects of study specified below, each course extending over a session of not less than five months, either continuous or divided into two terms, or, alternatively, one such course along with two courses, each extending over a session of not less than two and a half months During the fifth or final year the candidate shall be engaged in clinical study for at least nine months at the Infirmary of Dundee or at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised for the purpose by the University Court The candidate must have received instruction in each of the following subjects of study including such examinations as may be prescribed in the various classes—viz Anatomy, Practical Anatomy, Chemistry, Materia Medica Physiology, or Institutes of Medicine, Practice of Medicine, Surgery, Midwifery and the Diseases peculiar to Women and Infants, Pathology, Practical Chemistry, Physics (including the Dynamics of Solids, Liquids, and Gases, and the Rudiments of Sound, Heat, Light, and Electricity), Elementary Botany, Elementary Zoology, Practical Physiology, Practical Pathology, Forensic Medicine and Public Health The candidate must have attended for at least three years the Medical and Surgical Practice either of the Infirmary of Dundee or of a General Hospital elsewhere which accommodates not fewer than 80 patients and possesses a distinct staff of physicians and surgeons and is recognised for the purpose by the University Court Additional subjects of study are Practical Pharmacy, Mental Diseases, Practical Midwifery (12 cases of labour), Vaccination, Children's Diseases, Fevers, Ophthalmology, and Post mortem Examinations

With respect to the places and institutions at which the studies of the candidate may be prosecuted the following regulations shall have effect —1 Two of the five years of medical study must be spent in the University of St Andrews 2 The remaining three years may be spent in any University of the United Kingdom or in any Indian, Colonial, or Foreign University recognised for the purpose by the University Court, or in such medical schools or under such teachers as may be recognised for the purpose by the University Court

Women shall be admitted to graduation in Medicine, subject to the provisions of Ordinance No 18 [General No 9—Regulations for the Graduation of Women and for their Instruction in the Universities] Provided always that every candidate for graduation shall produce evidence of having satisfied the conditions herein laid down with respect to the Preliminary Examination, and shall be examined in all the subjects necessary for graduation by the Examiners of the University of St Andrews All the classes necessary for graduation shall be taken in the University of St Andrews, except in so far as instruction obtained elsewhere is allowed by the said Ordinance

Professional Examinations for the Degrees of Bachelor of Medicine and Bachelor of Surgery —Each candidate shall be examined both in writing and orally, and also clinically where the nature of the subject admits, in the following divisions—viz, First, in Botany, Zoology, Physics, and Chemistry, Second, in Anatomy, Physiology, and Materia Medica, Third, in Pathology, and Forensic Medicine and Public Health, Fourth, in Surgery and Clinical Surgery, Practice of Medicine and Clinical Medicine and Midwifery

The fee to be paid for the degrees of Bachelor of Medicine and Bachelor of Surgery shall be 22 guineas, and the proportion of this sum to be paid by a candidate at each division of the examination shall be regulated from time to time by the University Court The fee to be paid for the degree of Doctor of Medicine shall be 10 guineas, exclusive of any stamp duty which for the time may be demanded The fee to be paid for the degree of Master of Surgery shall be 10 guineas

The whole medical curriculum can be taken in University College or the first two years in United College

Bursaries United College, St Andrews —Fourteen Taylour Thomson Bursaries for female Medical students of the annual value of from £20 to £30 each, tenable for one or two years The Bursaries are awarded in the order of merit, the most valuable ones being given to those students who obtain the highest marks in the Preliminary Examination, and who are prepared to take two Anni Medici at the United College, St Andrews

University College Dundee —(*a*) Open to either sex Eleven Entrance Bursaries of £15 tenable for one year (*b*) Open to either sex Four £20 and three £15, second year (*c*) Four £20 and two £15 third year (*d*) Bute Bursary, founded in 1893 by the late Most Honourable the Marquis of Bute K T This Bursary consists of the free proceeds of £1000 (*e*) Two Bursaries of the annual value of £25 tenable for three years at either University College, Dundee, or at any Scottish University (local candidates only)

For further particulars apply to the Dean of the Medical Faculty, University College, Dundee, N B

UNIVERSITY OF DUBLIN (TRINITY COLLEGE)

Matriculation —All students in the School of Physic intending to practise Physic must be matriculated, for which a fee of 5*s* is payable No student can be admitted for the winter course after Nov 25th.

Degrees in Medicine (M B), Surgery (B Ch), and Midwifery (B A O) —Candidates for these degrees must be of B A standing and must be for at least five academic years on the books of the Medical School, reckoned from the date of matriculation The Arts course may be concurrent with the medical course, and the B A degree need not be taken before the final medical examinations, but the medical degrees are not conferred without the Arts degree The following courses must be attended —(1) Lectures — Systematic, Practical and Applied Anatomy, Chemistry and Practical Chemistry Surgery and Operative Surgery, Histology Botany, Zoology, Physics, Physiology and Practical Physiology, Practice of Medicine, Midwifery, Pathology, Materia Medica and Therapeutics, Medical Jurisprudence and Hygiene, (2) three courses of nine months' attendance on the Clinical Lectures of

Sir Patrick Dun's or other recognised Dublin Hospital (one year at a recognised London or Edinburgh hospital before the commencement of the Dublin curriculum may be counted as one year spent in such Dublin hospital) (3) Practical Vaccination, one month's instruction (4) Mental Disease, three months', (5) Practical Midwifery with Clinical Lectures, including not less than 30 cases six months', (6) Ophthalmic Surgery three months Two examinations have to be passed The Previous Medical or Half M B Examination, including Physics and Chemistry Botany and Zoology Anatomy and Institutes of Medicine (Practical Histology and Physiology), may be passed when credit has been obtained for the corresponding subjects, and these may be taken separately if desired The Final Examination is subdivided into five sections comprising Applied Anatomy (Medical and Surgical) Applied Physiology Jurisprudence and Hygiene, Materia Medica and Therapeutics, Medicine Surgery Pathology Midwifery Gynæcology Obstetrical Anatomy Clinical Medicine Mental Diseases, Clinical Surgery Operations Clinical Ophthalmology The first seven of these subjects may be passed in the fourth year and the last eight in the fifth year Fee for the *Liceat ad Examinandum* £10 Fee for the degrees, £17

Doctor in Medicine —A Doctor in Medicine must have passed all the qualifying examinations and must be a B A. of three years standing He must also read a thesis before the Regius Professor of Physic. Total amount of fees for this degree, £13

Master in Surgery —A Master in Surgery must be a Bachelor in Surgery of the University of Dublin of not less than three years standing and must produce satisfactory evidence of having been engaged for not less than two years from the date of his registration in the study or study and practice, of his profession He must then pass an examination in the following subjects —1 Clinical Surgery 2 Operative Surgery 3 Surgical Pathology 4 Surgery 5 Surgical Anatomy (on the dead subject) and one of the following optional subjects —1 Surgery in one of the following branches—viz. Ophthalmic and Aural, Gynæcological, and Dental. 2. Mental Disease 3 Medical Jurisprudence and Hygiene. 4. Advanced Anatomy and Physiology 5 Comparative Anatomy Fee for the degree of Master in Surgery, £11

Master in Obstetric Science —A Master in Obstetric Science must be fully qualified and produce a certificate of having attended a summer course in Obstetric Medicine and Surgery[1] He is then required to pass an examination in the following subjects —1 Practice of Midwifery 2. Gynæcology 3. Anatomy of Female Pelvis and Elementary Embryology 4 Clinical Gynæcology Fee for the degree of Master in Obstetric Science £5

University Diplomas —Candidates for the diplomas in Medicine, Surgery or Obstetric Science must be matriculated in Medicine, and must have completed two years in Arts and five years in Medical Studies The Course and Examination necessary for the diplomas are the same as for the degrees, except that the candidate is not required to attend the Lectures on Botany and Zoology nor to pass the Previous Medical examination in those subjects. A diplomate, on completing his course in Arts and proceeding to the degree of B A., may become a Bachelor by attending the Lectures on Botany and Zoology passing the Previous Medical examination in those subjects, and paying the degree fees Fee for the *Liceat ad Examinandum*, £10 Fee for the diplomas in Medicine, Surgery and Midwifery £11

ROYAL UNIVERSITY OF IRELAND

All Degrees Honours, Exhibitions, Prize Scholarships and Studentships in this University are open to students of either sex

Candidates for any degree in this University must have passed the Matriculation Examination Students from other universities and colleges are included in this rule.

The following degrees, &c. are conferred by the University in this Faculty —Bachelor of Medicine. Doctor of Medicine, Bachelor of Surgery Master of Surgery Bachelor of Obstetrics and Master of Obstetrics in Sanitary Science a special diploma and in Mental Disease a special diploma.

The Medical Examinations except those for the diplomas in Sanitary Science and Mental Diseases are held twice yearly —namely in April or May and in September or October The examination for the diploma in Sanitary Science is held in June or July

The course for degrees in Medicine &c., is of at least five years duration.

The First Examination in Medicine —Students may be admitted to this examination after the lapse of one academical year from the time of their matriculation They must also have previously passed the First University Examination and completed the first year of the medical curriculum. The subjects of this examination are Natural Philosophy Systematic Chemistry Zoology and Botany The examination in each subject will comprise three parts:—(1) a written examination, (2) an oral examination, and (3) a practical examination For Chemistry the practical examination forms part of the Second Examination in Medicine Particular weight will be given to the practical part of the examination Candidates at the First Examination in Medicine who at the First University Examination did not obtain 30 per cent of the marks assigned to French or German will be required to present themselves for a qualifying examination in French or German. Failure to obtain 30 per cent of the marks assigned to either of those languages will involve the loss of the examination.

The Second Examination in Medicine —Students will be admitted to this examination after the lapse of one medical year from the time of passing the First Examination in Medicine, provided they have completed the second year of the medical curriculum The subjects for this examination are Anatomy Physiology and Practical Chemistry

The Third Examination in Medicine —Students will be admitted to this examination after the lapse of one medical year from the time of passing the Second Examination in Medicine, provided they have completed the third year of the medical curriculum The subjects for this examination will be Anatomy Physiology and Materia Medica (Pharmacology and Therapeutics)

The Examination for the Medical Degrees —Students will be admitted to this examination after the lapse of not less than one medical year from the time of passing the Third Examination in Medicine provided they have completed the course of medical studies prescribed for the entire medical curriculum The examination consists of three parts or divisions —(*a*) Medicine, including Therapeutics and Pathology Mental Diseases, Medical Jurisprudence and Hygiene (*b*) Surgery Theoretical, Clinical, Operative Surgical Anatomy with Ophthalmology and Otology Surgical Pathology (*c*) Midwifery and Gynæcology with Diseases of Children. Each part of this examination must be passed as a whole Upon completing satisfactorily his examination in all three divisions the candidate will, in addition to the parchment diplomas recording his admission to the Medical Degrees of M B B.Ch., and B A O receive a certificate of having passed a qualifying examination in the subjects of Medicine Surgery and Midwifery The fee for this certificate is £10 which must be paid prior to the candidate's admission to the Medical Degrees.

M D Degree —Candidates may present themselves for the examination for this degree after the lapse of three academical years from the time of obtaining the degree of M B They must at the same time produce a certificate of having been for at least two academical years engaged in hospital or private medical, surgical, or obstetrical practice or in the military or naval medical service Every candidate will be examined at the bedside and required to diagnose at least three medical cases and prescribe treatment and to write detailed reports on at least two cases to be selected by the examiners and to discuss the questions arising thereon

The M Ch Degree —This degree will be conferred only on graduates in Medicine of the University of at least three years standing They must at the same time produce a certificate of having been for at least two academical years engaged in hospital or private medical surgical or obstetrical practice, or in the military or naval medical service The examination for this degree will comprise Surgical Diseases and Surgery both theoretical and operative, Surgical Anatomy Ophthalmology and Otology and will include—(*a*) a written examination (*b*) a clinical examination (*c*) an examination on Surgical Instruments and Appliances and (*d*) an examination in Operative Surgery

The M A O Degree —This degree will be conferred only on graduates in Medicine of the University of at least three years' standing They must at the same time produce a certificate of having been, for at least two academical years, engaged in hospital or private, medical, surgical, or obstetrical practice, or in the military or naval military service The examination will comprise the Theory and Practice of Midwifery and of Diseases of Women and Children and the Use of Instruments and Appliances and will include—(*a*) a written examination, (*b*) a clinical examination as far as practicable, (*c*) an oral examination, with practical illustrations, and (*d*) an examination on Instruments and Appliances.

---

[1] Existing graduates in Medicine of the standing of M.D are not required to attend this course

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGE OF PHYSICIANS OF LONDON AND THE ROYAL COLLEGE OF SURGEONS OF ENGLAND [3]

Regulations relating to the several Examinations applicable to Candidates who commenced their Professional Education on or after Jan. 1st, 1892

Any candidate who desires to obtain both the licence of the Royal College of Physicians of London and the diploma of Member of the Royal College of Surgeons of England is required to complete five years of professional study at recognised Medical Schools and Hospitals and to comply with the following regulations and to pass the examinations hereinafter set forth (One of the five years may be spent in an Institution recognised by the Board for instruction in Chemistry, Physics, Practical Chemistry, and Biology)

Professional Examinations —There are three Examinations, called herein the First examination, the Second examination, and the Third or Final examination, each being partly written, partly oral, and partly practical These examinations will be held in the months of January, April, July and October, unless otherwise appointed Every candidate intending to present himself for examination is required to give notice in writing to Mr F G Hallett, secretary of the Examining Board, Examination Hall, Victoria Embankment, W C, fourteen clear days before the day on which the examination commences, transmitting at the same time the required certificates

The subjects of the First examination are—Chemistry and Physics, Practical Pharmacy, and Elementary Biology A candidate may take this examination in three parts at different times A candidate will be admitted to examination in Chemistry and Physics, in Practical Pharmacy, and Elementary Biology, on producing evidence of having passed the required Preliminary examination and of having received instruction in these subjects at a recognised institution, *or he may take Pharmacy* at any time during the curriculum A candidate rejected in one part or more of the First examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection, and he will be re-examined in the subject or subjects in which he has been rejected If referred in Chemistry or Biology he must produce evidence of further instruction at a recognised institution Any candidate who shall produce satisfactory evidence of having passed an examination for a degree in Medicine on any of the subjects of this examination conducted at a university in the United Kingdom, in India, or in a British colony will be exempt from examination in those subjects in which he has passed

The fees for admission to the First examination are as follows For the whole examination, £10 10*s*, for re examination after rejection in Part I, £3 3*s*, and for re examination in each of the other parts, £2 2*s*

The subjects of the Second examination are Anatomy and Physiology Candidates will be required to pass in both subjects at one and the same time Candidates will be admissible to the Second examination at the expiration of two winter sessions and one summer session (or fifteen months during the ordinary sessions) from the date of passing the Preliminary examination, and after the lapse of one Winter and one Summer Session from the date of Parts I and III of the First examination on of the required certificates of professional study referred on the Second examination will be being admitted to re-examination, to pro- he has pursued, to the satisfaction of his teachers, in a recognised place of study, his Anatomical and Physiological studies during a period of not less than three months subsequently to the date of his reference

The fees for admission to the Second examination are £10 10*s* for the whole examination, and £6 6*s* for re-examination after rejection

The subjects of the Third or Final examination are Part I Medicine, including Medical Anatomy, Pathology, Practical Pharmacy, Therapeutics, Forensic Medicine, and Public Health Candidates who have passed in Practical Pharmacy at the First examination will not be re-examined in that subject at the Third examination Part II Surgery, including Pathology, Surgical Anatomy, and the use of Surgical Appliances Part III Midwifery and Diseases Peculiar to Women Candidates may present themselves for examination in Midwifery and Diseases of Women at any time after the completion of the fourth year of professional study at a Medical School and Hospital, not less than one year after passing the Second examination, on production of the required certificates Candidates may take this examination in three parts at different times, or they may present themselves for the whole examination at one time They will be required to produce the following evidence before being admitted to the several parts of the Third, or Final examination—viz, in Medicine of having attended Lectures on Medicine Pathology including Bacteriology, Pharmacology and Therapeutics, Forensic Medicine, and Public Health, Practical Instruction in Medicine, Medical Hospital Practice during two winter and two summer sessions, Demonstrations in the Post mortem Room during 12 months, Clinical Lectures on Medicine during nine months, of having discharged the duties of Medical Clinical Clerk, Practice or a Fever Hospital and Clinical Demonstrations at a recognised Lunatic Asylum, in Surgery, of having attended Lectures on Surgery and Pathology including Bacteriology, Practical Instruction in Surgery, of having performed operations upon the Dead Subject; Surgical Hospital Practice during two winter and two summer sessions, Demonstrations in the Post-mortem Room during 12 months, Clinical Lectures on Surgery during nine months, of having discharged the duties of Surgical Dresser, and Clinical Instruction in Opthalmology, in Midwifery of having attended Lectures on Midwifery, Practical Instruction in Midwifery, Clinical or other Lectures, with Practical Instruction in Diseases Peculiar to Women, and of attendance on 20 Labours

Fees for admission to the Third or Final examination are as follows For the whole examination, £21 Part I *For re examination in Medicine, including Medical Anatomy*, Pathology, Therapeutics, Forensic Medicine, and Public Health, £5 5*s*, for re examination in Practical Pharmacy (if taken at this examination), £2 2*s* Part II For re examination in Surgery, including Pathology Surgical Anatomy, and the use of Surgical Appliances, £5 5*s* Part III For re-examination in Midwifery and Diseases Peculiar to Women, £3 3*s*

A candidate referred on the Third or Final examination will not be admitted to re-examination until after the lapse of a period of not less than three months from the date of rejection and will be required, before being admitted to re examination, to produce a certificate, in regard to Medicine and Surgery, of having attended the Medical and Surgical Practice, or the Medical or Surgical Practice, as the case may be, during the period of his reference, and in regard to Midwifery and Diseases Peculiar to Women a certificate of having received subsequently to the date of his reference, not less than three months' instruction in that subject by a recognised teacher

ROYAL COLLEGES OF SURGEONS AND PHYSICIANS OF EDINBURGH AND FACULTY OF PHYSICIANS AND SURGEONS OF GLASGOW

These Colleges have made arrangements by which, after one series of examinations, held in Edinburgh or in Glasgow, or in Edinburgh and Glasgow, the student may obtain the diplomas of the three Bodies

The three Bodies grant their Single Licences only to candidates who already possess legal qualifications in Medicine or Surgery Copies of the Regulations for the Single Licence of any of the Bodies may be had on application to the respective secretaries

Professional Education —1 Candidates who commenced

---

of the Royal College of Surgeons of
Ophthalmic College of Physicians of London
to students who commenced
the places an

medical study *before* Jan 1st, 1892, must have been engaged in professional study during 45 months from the date of registration as medical students by the General Medical Council which period shall include not less than four winter sessions attendance at a recognised medical school. 2. The candidate must produce certificates or other satisfactory evidence of having attended the following separate and distinc courses of instruction Anatomy during at least six months, Practical Anatomy twelve months, Chemistry six months Practical or Analytical Chemistry, three months Materia Medica, three months, Physiology, six months, Practice of Medicine six months, Clinical Medicine, nine months, Principles and Practice of Surgery six months Clinical Surgery nine months, Midwifery and the Diseases of Women and Children, three months, Medical Jurisprudence, three months, Pathological Anatomy three months The six months' courses delivered in Scotland must consist of not fewer than 100 lectures The three months courses must consist of not fewer than 50 lectures The number of lectures certified as attended at any school not situated in Scotland should not be less than three-fourths of the total number of lectures delivered in a course. 3. The candidate must also produce the following certificates —(*a*) Of having attended not less than six cases of labour three of these to be conducted personally under the direct superintendence of the practitioner who signs the certificate who must be a registered medical practitioner (*b*) Of having attended, for three months, instruction in Practical Pharmacy the certificate to be signed by the teacher who must be a member of the Pharmaceutical Society of Great Britain, or the superintendent of the laboratory of a public hospital or dispensary or a registered practitioner who dispenses medicines to his patients, or a teacher of a class of Practical Pharmacy (*c*) Of having attended for 24 months the *Medical* and Surgical practice of a public general hospital containing on an average at least 80 patients available for clinical instruction and possessing distinct staffs of physicians and of surgeons. (*d*) Of having attended for six *months (or three months, with three months* hospital clerkship) the practice of a public dispensary specially recognised by any of the above authorities, or the out patient practice of a recognised general hospital or of having acted for six months as pupil to a registered practitioner who either holds such a public appointment, or has such opportunities of imparting practical knowledge as shall be satisfactory to the coöperating authorities this attendance should be made after the student has passed the First and Second examinations. (*e*) Of having been instructed by a registered medical practitioner in the Theory and Practice of Vaccination, and of having performed operations under the teacher s inspection during a period of not less than six weeks

Candidates shall be subjected to three Professional examinations, and they may enter either for the whole of an *examination or for a division thereof*

First Examination —The First examination shall embrace the two divisions of (1) Chemistry and (2) Elementary Anatomy and Histology and shall take place not sooner than the end of the first year including the period of a winter and a summer session For the whole examination taken at one time the sum of £5 5*s* must be paid to the inspector of certificates not later than one week preceding it, after which no candidate will be entered. After rejection for re-entry in all subjects £3 3*s* for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s*. for entering for one division of subjects *separately* £3 3*s* and for each re-entry after rejection, £2 2*s* Any candidate who shall produce satisfactory evidence of having passed an equivalent examination in any of the subjects of the First examination before any of the boards specified in the Regulations will be exempt from examination in such subjects

Second Examination.—The Second examination shall embrace the three subjects of (1) Anatomy (2) Physiology (3) Materia Medica and Pharmacy each of which shall constitute a division of the examination and may be entered for separately The examination shall not take place before the termination of the summer session of the second year of study including two winters and two summers The fees for admission to this examination payable not later than one week before the day of examination, are as *follows* —*For the* whole examination, £5 5*s* after rejection for re-entry in all subjects, £3 3*s* for re-entry after obtaining exemption from re-examination in one or two subjects, £2 2*s*. for entering for one subject separately £2 2*s* and for each re-entry therein after rejection, £2 2*s* Any candidate who shall produce *satisfactory evidence of having* passed an equivalent examination in any of the subjects of the Second examination before any of the boards specified in the Regulations will be exempt from examination in such subject or subjects

Final Examination —The Final examination shall embrace the three divisions of—(1) the Principles and Practice of Medicine (including Therapeutics, Medical Anatomy and Pathology) and Clinical Medicine (2) the Principles and Practice of Surgery (including Surgical Anatomy and Surgical Pathology) and Clinical Surgery (3) Midwifery and Gynæcology Medical Jurisprudence, and Hygiene (which divisions may be entered for separately at different times) and shall not take place before the termination of the full period of study The fees for this examination, payable not later than one week before the examination day are as follows For the whole examination, taken at one time, in the case of candidates who have passed the First and Second examinations £15 15*s* of which £10 10*s* shall be returned to unsuccessful candidates For entering for each of the three divisions of subjects separately £6 6*s* and on re-entry after rejection £2 2*s* in respect of each division or part thereof This rule will also apply to any subsequent rejection. Any candidate admitted to the Final examination on the footing of having passed in the subjects of the First and Second examinations at a recognised board, shall on entering pay the full fee of £26 5*s*

All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery which shall include the Examination of Patients Physical Diagnosis, the Clinical Use of the Microscope, Examination of the Urine and Urinary Deposits Surgical Appliances, Bandages, Surface Markings, &c.

REGULATIONS FOR CANDIDATES WHO COMMENCED STUDY *after* JANUARY 1ST 1892

In addition to the courses above prescribed candidates are required to attend the following courses Physics three months, Elementary Biology three months, Diseases and Injuries of the Eye three months Insanity three months Infectious Diseases three months and a third year of Hospital Practice with Clinical Instruction (which may include the study of special diseases)

The curriculum lasts for five years, the fifth year should be devoted to clinical work at one or more public hospitals or dispensaries Six months of the fifth year may be passed by the student as a pupil to a registered practitioner possessing such opportunities of imparting practical knowledge as may be deemed satisfactory by the Committee of Management *The student s regularity of attendance in the wards and out* patient departments of the hospitals and at the post mortem examinations should be duly ascertained and noted on the certificate.

Candidates shall be subjected to four professional examinations

First Examination —The First examination shall embrace the following divisions of subjects—(1) Physics (2) Chemistry and (3) Elementary Biology The fees payable for admission to the First examination shall be for the whole examination £5 for each division separately £2 10

Second Examination.—The Second examination shall embrace Anatomy and Physiology including Histology and candidates may be admitted to this examination at the end of the second year of medical study The fees payable for admission to the Second examination *shall be—for the whole examination, £5*

Third Examination —The Third examination shall embrace Pathology and Materia Medica with Pharmacy The fees payable for admission to the Third examination shall be—for the whole examination £5 for re-entry in both subjects after rejection, £3

Final Examination —The Final examination shall not be passed earlier than the end of the fifth year of study and shall embrace the following subjects —Medicine including Therapeutics Medical Anatomy and Clinical Medicine Surgery including Surgical Anatomy Clinical Surgery and Diseases and Injuries of the Eye Midwifery and *Diseases of Women and of New born Children* and Medical Jurisprudence and Public Health All candidates shall be subjected, in addition to the written and oral examinations, to clinical examinations in Medicine and Surgery which shall include the Examination of Patients, Physical Diagnosis, the *Clinical* use of the Microscope Examination of the Urine and Urinary Deposits, Surgical

Appliances, Bandages, Surface markings, &c. The fees payable for the Final examination shall be,—for the whole examination, £15, for re entry in all subjects after rejection, £5

There are six periods of examination annually, four in Edinburgh and two in Glasgow, and candidates may present themselves at either examining centre irrespectively of the place of the previous examination The Registrar in Edinburgh is Mr J Robertson, Solicitor, 54 George square, and the Registrar in Glasgow, Mr A. Duncan, LL D, 242, St Vincent-street, to whom fees and certificates must be sent

Note —In applying for copies of the Regulations students should state whether they commenced medical study before or after Jan 1st, 1892.

ROYAL COLLEGE OF SURGEONS OF EDINBURGH

The Royal College of Surgeons of Edinburgh admits to the examination for its single Licence any candidate who already holds a Diploma in Medicine of any British Indian, or Colonial university or of any British or Colonial College of Physicians, or of the Society of Apothecaries of London or Apothecaries' Hall, Dublin, granted under the provisions of the Medical Act, 1886, whose preliminary examination and course of professional study is proved to be sufficient to fulfil the requirements of the College, or to those who have passed a full examination for any of the above Female practitioners are now admitted to the Licence of the College but not to the Fellowship, and the regulations for the licence apply to practitioners of either sex

Every candidate for a surgical diploma must have followed his course of study in a university, or in an established school of medicine, or in a provincial school specially recognised by the College of Surgeons of that division of the United Kingdom in which it is situate

Under the title Established School of Medicine are comprehended the medical schools of those cities of Great Britain and Ireland in which Diplomas in Surgery are granted, and such colonial and foreign schools as are similarly circumstanced in the countries in which they exist

PROFESSIONAL EXAMINATION FOR THE DIPLOMA OF THE COLLEGE

Candidates for the Diploma of the College will be subjected to one professional examination, partly in writing and partly practically and orally

Opportunities for the examinations will be presented four times in each year On each of these occasions the candidates will assemble to write answers to the questions proposed and the clinical and oral examinations shall be conducted on the days immediately succeeding

Unsuccessful candidates will be remitted to their studies for a period to be determined by the judgment of the examiners, but not in any case for less than three months

The examination will embrace the principles and practice of surgery (including operative surgery and surgical pathology), clinical surgery, and surgical anatomy, and will not take place before the termination of the full period of study

Applications for examination must be made to Mr James Robertson, solicitor, 54, George square, Edinburgh clerk to the College, not later than one week prior to the date of examination

On the production of the required document Mr Robertson will give the candidate an order authorising the examiners to admit him to examination

The fee of £15 15*s* payable to the College must be lodged in the hands of Mr Robertson not later than one week preceding the examination day The sum of £10 10*s* will be returned to each unsuccessful candidate Under special circumstances candidates can be examined on days other than those fixed by the regulations The fee for a special examination is as follows, viz, £20 for examination, of which £10 will be returned to candidates remitted on examination

In order to test more effectually the practical knowledge of candidates recent dissections and anatomical specimens will be employed during examination They will also be subjected to a practical clinical examination in the Surgical Hospital, including the application of surgical apparatus, bandages surface markings, &c, and may, if it be considered necessary to test their knowledge, be required to perform operations on the dead body

ROYAL COLLEGE OF PHYSICIANS OF EDINBURGH

The Royal College of Physicians of Edinburgh grants its single Licence on terms similar to those of the Royal College of Surgeons of Edinburgh, as above mentioned

SOCIETY OF APOTHECARIES OF LONDON

There are two examinations—Primary and Final The Final examination is divided into Section I and Section II The Primary examination is held quarterly, on the first Wednesday and on the Monday and Thursday of the same week, in the months of January, April, July, and October Final examinations are held monthly

The Primary examination consists of two parts Part I Elementary Biology, Chemistry, Chemical Physics, including the Elementary Mechanics of Solids and Fluids, Heat, Light, and Electricity, Practical Chemistry, and Materia Medica and Pharmacy A synopsis indicating the range of the subjects in the examination will be sent with the regulations on application Evidence of instruction in these subjects must be produced prior to examination Part II includes Anatomy, Physiology, and Histology This examination cannot be passed before the completion of twelve months' Practical Anatomy with Demonstrations, and these subjects cannot be taken separately except in the event of the candidate having previously passed in one. Evidence must be produced of the candidate's course of study A schedule for the Primary examination, to be obtained of the Secretary, must be signed by the Dean of the Medical School or other authority Section I of the Final examination consists of three parts Part I includes the Principles and Practice of Surgery, Surgical Pathology, and Surgical Anatomy, Operative Manipulation, Instruments, and Appliances Part II includes the Principles and Practice of Medicine, Pharmacology, Pathology and Morbid Histology, Forensic Medicine, Hygiene, Theory and Practice of Vaccination, and Mental Diseases Part III includes Midwifery, Gynæcology, and Diseases of New born Children and the Use of Obstetric Instruments and Appliances Section I of the Final examination cannot be passed before the expiration of 45 months after registration as medical student, during which time not less than three winter sessions and two summer sessions must have been passed at one or more of the medical schools connected with a general hospital recognised by the Society Section II of the Final examination consists of two Parts Part I Clinical Surgery, Part II Clinical Medicine and Medical Anatomy Section II cannot be passed before the end of the fifth year

The course of study for the Primary examination is as follows —Elementary Biology, not less than three months, Chemistry and Chemical Physics, six months, Practical Chemistry, three months, Pharmacy and Dispensing, three months, Anatomy, six months, Practical Anatomy with Demonstrations twelve months, Physiology, six months, Histology with Demonstrations, three months The study of these subjects must be pursued at a Medical School recognised by the Society Instruction in Pharmacy and Dispensing must be given by a registered medical practitioner or by a member of the Pharmaceutical Society by examination or in a public hospital, infirmary, or dispensary

The course of study for the Final examination, Section I, includes attendance on the Surgical and Medical Practice (with Post-mortem Examinations) at a hospital connected with a medical school for a period of one winter and one summer session, lectures on the Principles and Practice of Surgery, six months, Practical Surgery, three months, Clinical Surgical Lectures, nine months, Dressership, six months, Performance of Surgical Operations on the Dead Body, lectures on Principles and Practice of Medicine, six months, Pathology, three months, Clinical Medical Lectures, nine months, Clinical Clerkship,[4] six months, Forensic Medicine, Hygiene, and Insanity, three months, Midwifery and Gynæcology, three months, Clinical Instruction in the same, three months, a course of Practical Midwifery, attendance on 20 Midwifery cases The course of medical study must extend over the above-mentioned period of 45 months

The course of study for the Final examination Section II includes either attendance on the Practice of Medicine and Surgery at a hospital or other institution recognised by the Society for a further period of 12 months or six months as above and six months as a pupil of a registered practitioner holding a public medical or surgical appointment, or attendance at two special hospitals for six months (three months at each hospital) and for six months at a general hospital, all such hospitals to be recognised by the Society Evidence shall also be given of practical instruction in Infectious Diseases and in Mental Diseases (at a lunatic asylum or in the wards of an institution containing a special ward set apart for the treatment of mental diseases), and in any two of the following subjects Ophthalmic Surgery Laryngology with Rhinology and Otology Dermatology and Diseases of Children No candidate is eligible for the Final examination who has not completed the curriculum prescribed by the Society in evidence of which a schedule, to be obtained of the Secretary must be produced, signed by the Dean of the Medical School or other authority Prior to Section II of the Final examination the candidate must produce certificates (1) of being 21 years of age, (2) of moral character, (3) of the course of medical study, and (4) *of proficiency in vaccination signed by a teacher* authorised by the Local Government Board. Candidates intending to present themselves for examination are required to give 14 days notice. A form for this purpose will be sent on application.

---

[4] These offices must be held at a hospital or other institution recognised by the society

The fee for the Licence is 20 guineas The examination offices are open from 10 A.M to 4 P M on Saturdays *from* 10 A.M to 1 P M *All letters should be addressed to* the Secretary Court of Examiners, Society of Apothecaries of London, Blackfriars, E C.

APOTHECARIES HALL OF IRELAND

The Licence of this Hall is granted to students who can present certificates of having fully completed the course of study as laid down in the curriculum The diploma of the Apothecaries Hall of Ireland entitles the holder to be registered as a practitioner in medicine, surgery and midwifery also with the privileges of the Apothecary Licence There are four professional examinations, the total fees in connexion with which amount to 21 guineas Ladies are eligible for the diploma. Candidates already on the Register will receive the diploma of the Hall upon passing an examination in the subjects which are not covered by their previous qualifications and on paying a fee of 10 guineas If medicine or surgery be required two guineas extra will be charged

The fees payable for each examination are as follows — first professional £5 5*s* second, £5 5*s*. third £5 5*s* final examination £6 6*s* *If a candidate gives three clear* days' notice of inability to attend he may present himself at the ensuing examination without any further fee. A candidate is allowed for each professional examination which he has completed at any other licensing body except the final. If he has passed only in some of the subjects in a given examination he has to pay the whole of the fee for that examination *The fees for re*-examination *are for* each subject £1 1*s*., excepting in the subjects of chemistry pharmacy surgery medicine, second anatomy and ophthalmology the fees for which are two guineas each. The fee for the final alone is £15 15*s* when the other examinations have been taken elsewhere. All examination fees are to be lodged in the Sackville-street Branch of the Royal Bank of Ireland to the credit of the Examination Committee. Applications and schedules, together with bank receipt for the fee must be lodged with the Registrar Apothecaries Hall 40 Mary street Dublin, 14 clear days before the first day of examination.

There are four examinations—first, second third and final. The first three are held quarterly on the third Monday in January April July and October there are only two finals in January and July *The first examination includes* biology physics, theoretical and practical chemistry with an examination at the bench. Pharmacy is put down to this examination, but it may be taken at any of the first three examinations. Candidates holding a Pharmaceutical licence are exempt from this subject. Osteology (first anatomy) is also a subject of the first professional examination. The subjects for the second professional are anatomy of the whole body (the examination in this subject is practical) materia medica and therapeutics physiology and practical histology The third examination consists of pathology materia medica if not taken at second examination medical jurisprudence, and hygiene. The final examination includes medicine oral and clinical surgery including operations clinical and oral, clinical ophthalmic surgery midwifery and gynæcology Written papers are required on all these subjects.

Candidates who desire to obtain the Letters Testimonial of the Apothecaries Hall in Ireland must before proceeding to the final examination produce evidence of having been registered as medical students for 57 months also of having attended courses of instruction as follows —one course each (winter course of six months) of the following anatomy (lecture) chemistry (theoretical) midwifery practice of medicine physiology or institutes of medicine surgery, dissections two courses of six months each. Courses of three months materia medica medical jurisprudence chemistry (practical) practical physiology and histology operative surgery physics clinical ophthalmology biology clinical instruction in mental disease pathology and vaccination Medico-chirurgical hospital, 27 months to be distributed, at the student's own discretion over the last four years of his study The candidate may substitute for nine *months in this hospital attendance six months as a resident* pupil He will be required to present a certificate of having taken notes of at least six medical and surgical cases recorded under the supervision respectively of a physician and surgeon of his hospital Three months' study of fever—which may be included in his 27 months hospital attendance —in a hospital containing fever wards and having taken notes of five cases of fever—viz either typhus fever typhoid fever scarlet fever, small pox or measles Six months practical midwifery and diseases of women during the winter or summer of the third or the fourth year at a recognised lying in hospital or maternity Three months practical pharmacy in a recognised clinical hospital or a recognised school of pharmacy or a year in the compounding department of a licentiate apothecary or a pharmaceutical chemist. Each candidate before receiving his diploma must produce evidence that he has attained the age of 21 years Each candidate must produce evidence of having before entering on medical studies passed a preliminary examination in general education recognised by the General Medical Council and of having been registered by that Council as a student in medicine Certificates of medical study will not be recognised if the commencement of the course to which the certificate refers dates more than 15 days prior to such registration except in the subjects of physics or biology This registration is not undertaken by the Hall but the student must apply to the Registrar of the General Medical Council that he may be so entered The details of the course of education required and syllabus of the examina*tions will be supplied on application to the Registrar at* 40 Mary street Dublin.

UNIVERSITY OF BRUSSELS

British and other practitioners holding registrable qualifications are admitted to the examination for the Doctorate of the University of Brussels without further curriculum It is essentially a *practitioner's* examination and is separate from that intended for the Belgian students who take up the medical curriculum of the University The fees are—For matriculation £8 12*s* for 1st Part, £4 8*s*, for 2nd Part, £4 4*s* for 3rd Part, £4 8*s* for legalisation of diploma, 8*s* —total £22. Candidates who have paid in advance the *fees for* the three examinations, and are unsuccessful in the first, recover the fees paid for the second and third; *those who fail in the* second recover the fees paid for the third examination Unsuccessful candidates are allowed to come up again three months after rejection on payment of examination fees only provided this second appearance be in the course of the same academical year (October 1st to June 30th), otherwise they must renew the payment of the matriculation fee of £8 12*s* *There are three* examinations, viz —1st Part General Medicine, Pathology and Morbid Anatomy General Therapeutics, Materia Medica and Pharmacology Special Therapeutics and Mental Diseases 2nd Part Surgery Midwifery Hygiene and Medical Jurisprudence. 3rd Part Clinical examination in Medicine at the Hospital Clinical Surgical examination examination in Midwifery consisting of obstetrical operations on the mannequin (doll and model of pelvis), examination in Operative Surgery consisting of some of the usual operations on the dead subject, such as Amputation Ligature of an Artery &c.; Regional Anatomy on the Dead Body with Directions and Ophthalmology The first and second parts are theoretical and the third is mainly practical and clinical The time required for the three examinations seldom exceeds ten days, and is usually less Candidates have the option of passing each part separately or of taking the three together, and the latter is the usual course, also of demanding a written examination on payment of an additional fee of one guinea for each part, a rule of which candidates rarely or never avail themselves The examinations, which are *vivâ voce*, take place on the first Tuesday in November, December, February, May, and June Candidates should appear with their diplomas at the Secretary's office not later than 2 P M on the day preceding the examination Most of the examiners speak English and those who do not examine through the medium of an interpreter Great importance is attached to practical knowledge, but candidates must also possess sound theoretical knowledge, the standard required varying with the subject Pathological and other specimens are not usually shown Professor Rommelaere has resigned his appointments at l'Hôpital Saint Pierre and as an examiner in clinical medicine and his place has been taken by Professor Steinon who formerly examined in Pathology, There are in England at present over 600 graduates holding this degree, and an English Association of Brussels Medical Graduates has been in existence for many years

Further information may be obtained from Dr Walter Reeve, 2, Harewood-place, Hanover square, W

METROPOLITAN MEDICAL SCHOOLS[1]

ST BARTHOLOMEW'S HOSPITAL AND COLLEGE —The clinical practice of the hospital comprises a service of 744 beds, of which 674 are for patients in the hospital at Smithfield and 70 for convalescent patients at Swanley Ten house physicians and ten house surgeons are appointed annually During their first six months of office they act as "junior" house physicians and house surgeons and receive a salary of £25 a year During their second six months they become "senior" house physicians and house surgeons and are provided with rooms by the hospital authorities and receive £80 a year as salary A resident midwifery assistant and an ophthalmic house surgeon are appointed every six months, and are provided with rooms and receive a salary of £80 a year Two assistant anæsthetists are appointed annually, and receive salaries of £120 and £100 respectively, with rooms An extern midwifery assistant is appointed every three months, and receives a salary of £80 a year Two assistant electricians are appointed every six months The clinical clerks, the obstetric clerks, the clerks to the medical out-patients, the dressers to the surgical in patients and to the out-patients, and the dressers in the special departments are chosen from the students All the appointments are now free

A college is attached to the hospital, in which students can reside, subject to the college regulations

The Medical School Buildings include three large lecture theatres, a large dissecting room, a spacious library (containing 13 000 volumes), a well appointed museum of anatomy, physiology, comparative anatomy, materia medica, botany, and pathological anatomy The pathological museum is the most complete in the kingdom. There are laboratories for chemistry, physiology, pathology, pharmacology, physics, public health, and biology, giving ample accommodation in every department.

The ground of 10 acres is at Winchmore-hill for the use of the Students' Amalgamated Clubs, and all students are expected to become members

Instruction in Preliminary Science is given to University of London students in chemistry, biology, and physics throughout the year

Laboratory Instruction for the D P H is provided during the winter and summer sessions, and elementary instruction in Bacteriology is also given throughout the year

Staff —Physicians Sir William Church, Bart, K C B, Dr Gee, Sir Dyce Duckworth, Dr Hensley, and Sir Lauder Brunton Consulting Surgeons Mr Holden, Sir T Smith, Bart, K C V O, and Mr Willett Consulting Ophthalmic Surgeon Mr H Power Surgeons Mr Langton, Mr Marsh, Mr Butlin, Mr Walsham, and Mr Harrison Cripps Assistant Physicians Dr Norman Moore, Dr S West, Dr Ormerod, Dr Herringham, and Dr Tooth, C M G Assistant Surgeons Mr Bruce Clarke, Mr Bowlby, C M G, Mr Lockwood, Mr D Arcy Power, and Mr Waring Physician Accoucheur Dr Champneys Assistant Physician Accoucheur Dr Griffith Ophthalmic Surgeons Mr Jessop and Mr Holmes Spicer Aural Surgeon Mr Cumberbatch Pathology Dr Andrewes Electrician Dr L Jones Dental Surgeons Mr Paterson and Mr Ackery Assistant Dental Surgeons Mr Read and Mr Ackland Anæsthetists Mr Gill and Mr E Willett Casualty Physicians Dr Thursfield and Dr Riviere

This hospital receives within its walls nearly 7000 in patients annually and its out-patients and casualties amount to more than 160,000 annually It comprises a service of 744 beds, of these 241 are allotted to the medical cases, 336 to the surgical, including orthopædic cases, 25 to diseases of the eye, 34 to diseases of women, 38 to isolation and general, and 70 at the Convalescent Hospital, Swanley Special departments have been organised for diseases of the eye, ear, larynx, and skin, as well as for Orthopædic and Dental Surgery Surgical operations every day at 1 30 P M Surgical consultations on Thursday, at 1.30 P M The physicians and surgeons deliver clinical lectures weekly during both the winter and the summer sessions Clinical Lectures on all special subjects are also given The visits of the physicians and surgeons are made at 1 30

Lecturers Winter Session.—Medicine Dr Norman Moore and Dr West Clinical Medicine Sir William Church, Bart., Dr Gee, Sir Dyce Duckworth, Dr Hensley, and Sir Lauder Brunton Surgery Mr Walsham and Mr Bowlby Clinical Surgery Mr Langton, Mr Marsh, Mr Butlin, Mr Walsham, and Mr Cripps Pathology Dr Andrewes Chemistry Dr Chattaway Descriptive and Surgical Anatomy Mr Bruce Clarke and Mr Waring Biology Dr Shore Physiology Dr E Klein and Dr Edkins Superintendents of Dissections Mr Rawling, Mr Douglas, Mr Harmer, Mr Murphy, and Mr C E West Demonstrators of Morbid Anatomy Dr Fletcher, Dr Drysdale, Mr Power, and the surgical registrar Demonstrators of Practical Surgery Mr Waring and Mr Bailey Operative Surgery Mr Power and Mr Bailey Demonstrators of Practical Physiology Dr Edkins, Dr Langdon Brown, and Dr Bainbridge Ophthalmic Demonstrators Mr Jessop and Mr Spicer Lecturer on Physics Mr F Womack. Practical Chemistry Dr Chattaway, Dr Orton, and Dr Hurtley

Summer Session.—Materia Medica and Therapeutics Dr Calvert Midwifery and Diseases of Women and Children Dr Champneys Botany Rev G Henslow Forensic Medicine Dr Hensley Pathology Dr Andrewes Ophthalmic Surgery Mr Jessop Practical Chemistry Dr Chattaway, Dr Orton, and Dr Hurtley Comparative Anatomy Dr T W Shore Psychology Dr Claye Shaw Public Health Dr Hamer Organic Chemistry Dr Chattaway Demonstrators of Operative Surgery Mr Power and Mr Bailey Morbid Anatomy Dr Andrewes, Dr Fletcher, Dr Drysdale, Mr Power, and the surgical registrar Diseases of Skin Dr Ormerod Diseases of the Eye Mr Jessop and Mr Holmes Spicer Diseases of the Ear Mr Cumberbatch Orthopædic Surgery Mr Bruce Clarke Diseases of Larynx Mr D'Arcy Power Demonstators of Medicine Dr Herringham, Dr Tooth, and Dr Horder Demonstrator of Midwifery Dr Robinson Tutor in Public Health Dr Warry Biological Demonstrators Dr Shore, Mr Beckton, and Mr Gauvain Bacteriology Dr Andrewes Pharmacy Dr Calvert and Dr H Smith Chemical Pathology Dr Garrod Medical Registrars Dr Fletcher and Dr Drysdale Surgical Registrar Mr Bailey

CHARING CROSS HOSPITAL AND COLLEGE —This hospital and convalescent home contain 260 beds, a certain proportion of which are set aside for the diseases of children and those special to women Total fees, 110 guineas if paid in a single sum on entry, or 121 guineas if paid in five instalments, the sons of Registered Medical Practitioners pay 100 guineas in one sum or 110 guineas in five sums, for Dental students, 54 guineas, or 60 guineas in two equal instalments General students pay proportionately lower fees, and are admitted without additional fee to the courses of Clinical Medicine and Surgery They are entitled to compete for the Scholarships, Gold Medal, Huxley, and Pereira Prizes

Classes for the Preliminary Scientific Examination of the University of London are held at this Medical School. The fee for the whole course, which begins in October, is

---

[1] For Scholarships see p 629 et seq

15 guineas There are also special classes for the practical work for the Department of Public Health and a course in the subject of Diseases of Tropical Climates

Staff —Consulting Physician Sir J Fayrer Bart. M D Consulting Obstetric Physician Dr J Watt Black Consulting Physician for Diseases of the Skin Dr Sangster Physicians Dr Green Dr Bruce and Dr Abercrombie Physicians to Out-patients Dr Willcocks Dr Murray and Dr. Mott. Assistant Physician Dr Galloway Consulting Surgeon Mr R. Barwell. Demonstrators in Anatomy Mr Howell Evans Mr Frazer and Mr Barwell. Assistant Demonstrators in Anatomy Mr Higgs and Mr Walford Demonstrator in Chemistry Mr Addyman Demonstrator in Materia Medica Mr Stark. Public Health (D P H) Mr Gardner Dr Slater and Dr Harold Spitta. Librarian Mr Alfred Lowe.

GUY'S HOSPITAL.—This hospital founded by Thomas Guy in 1721 for the reception of 400 patients, and enlarged through the aid of a large bequest from the late William Hunt, contains at the present time 690 beds and with its extensive buildings and grounds occupies an area of about six acres The hospital is divided into Medical Surgical Clinical, Ophthalmic and Gynaecological wards independently of separate rooms for special cases

House physicians house surgeons assistant house physicians, and assistant house surgeons obstetric residents gynaecological assistants clinical assistants, clerks to anaesthetists surgeons and assistant surgeons dressers surgical ward clerks, clinical clerks, post mortem clerks extern obstetric attendants and dressers and clerks in the special departments are appointed from among the students upon the recommendation of the medical staff, according to merit and without extra payment The house physicians of whom there are four hold office for six months each The assistant house physicians who hold office for three months attend in the out patient department four afternoons in the week and see all the cases not seen by the assistant physician of the day The house physicians have the care of the patients in the medical wards and attend to all emergencies arising in the absence of the physicians They are provided with board and lodging in the college free of expense The house surgeons of whom there are four hold office for six months each, and are provided with board and lodging in the college free of expense The surgical Casualty Department is in charge of two assistant house surgeons and there are four other assistant house surgeons appointed each three months The surgeons dressers are selected from those students who have completed their third winter session and have been most diligent in the junior appointments They hold office for three or six months Six are attached to each surgeon, and during their weeks of special duty they are provided with board and lodging in the hospital free of expense The obstetric residents, four in number, are provided with board and lodging in the college free of expense.

Higher Examinations—Classes are held throughout the year for the Preliminary Scientific Examination of the University of London, and special courses of instruction are provided for students preparing for the Primary and Final Fellowship examination and the intermediate M B examinations of Oxford, Cambridge, and London

The College—The College stands upon a site fronting the east gate of the hospital and is connected with it by a subway The building serves as a Residential College for Students and at the same time provides accommodation for the Students' Club The Clubs' Union ground is less than twenty-five minutes' journey from the hospital

Staff—Consulting Physicians Sir Samuel Wilks, Dr F W Pavy, Dr P H. Pye Smith, and Dr J F Goodhart, Physicians and Assistant Physicians Dr Frederick Taylor, Dr W Hale White, Dr G Newton Pitt Dr E C Perry, Dr L. E Shaw, Dr J H Bryant, Dr J Fawcett (Dean of the School), and Dr A P Beddard Consulting Surgeons Dr J Birkett, Mr Thomas Bryant and Sir H. G Howse Surgeons and Assistant Surgeons Mr R Clement Lucas, Mr C H. Golding Bird, Mr W H A. Jacobson, Mr Charters J Symonds, Mr W Arbuthnot Lane, Mr L A. Dunn, Mr A. Andrews As Emeritus Professor of Surgery Mr. Hutchinson will give in the Summer Session, and Sir Frederick Treves, Bart. will give in the Winter Session a course of lectures in Clinical Surgery The special subjects and the dates will be announced in due course. Dr Hewitt as Emeritus Lecturer on Anæsthetics, will give a course of lectures during the first half of the Winter Session. Warden Mr Munro Scott.

ST MARY'S HOSPITAL—The hospital contains 281 beds which number will be raised to 362 on completion of the Clarence wing The situation of the hospital in the centre of the residential districts of Paddington, Bayswater and North Kensington renders it especially convenient to students who wish to reside in the immediate vicinity and a register of approved lodgings is kept in the office of the Medical School All clinical appointments in the hospital are free to students of the Medical School and the resident medical officers are chosen by competitive examination Six house physicians six house surgeons, four obstetric officers and two resident anæsthetists are appointed in each year and receive board and residence in the hospital. Entrance scholarships in Natural Science one of £145 two of £78 15s one of £52 10s and two of £63 (open to students from Oxford and Cambridge) are awarded annually by examination in September

The New Wing—The new wing the ground floor of which comprising the new out-patient department was opened in 1898, is now in process of completion This will add to the hospital 81 new beds and will include additional operating theatres, a new clinical laboratory a clinical theatre and an x ray department

The Laboratories—The Physiological Laboratories have recently been enlarged and the Pathological Department further extended with the provision of special laboratories for the study of bacteriology and pathological chemistry

Special Tuition—In addition to systematic courses of lectures and demonstrations special tuition is provided for the Intermediate and Final Examinations of the Universities of Oxford Cambridge and London without additional fees

Preliminary Scientific Course—Special classes including lectures and laboratory work are held throughout the year

The composition fee for full students is £140 if paid in one sum, or £145 if paid in four instalments University students who have completed their examinations in Anatomy and Physiology are admitted on payment of a composition fee of 60 guineas (£63) paid in one sum or by payment of two annual instalments of 35 guineas (£36 15s) and 30 guineas (£31 10s) respectively University students who have not completed their examination in Anatomy and Physiology pay an annual fee of 25 guineas (£26 5s) until they have passed these examinations and then pay the composition fee Separate courses of lectures laboratory work, or hospital practice may be taken The composition fees include membership of the amalgamated clubs The School Calendar and full information can be obtained from the Secretary St Mary's Hospital Medical School, Paddington, W

MIDDLESEX HOSPITAL —The hospital contains 340 beds There is a special wing for patients suffering from cancer, consisting of four wards, containing 40 beds , here cancer patients are received and attended for a period limited only by the duration of their disease

Hospital Appointments —All hospital appointments are allotted to students without any extra fee Eighteen Resident Appointments are annually filled from the pupils of the hospital, each appointment extending over six months Special Classes are held to prepare students for the Inter M B (Lond) Examination and for the Primary Examination for the diploma of F R C S Eng

The Hospital and Medical School are fully equipped for the theoretical and practical teaching of all the subjects included in the examinations in Medicine and Surgery in the United Kingdom and for the diploma in Public Health, and ample laboratory and class room accommodation is provided for the teaching of the various subjects of the curriculum and for original research in Medicine, Pathology, or Bacteriology

A Residential College to accommodate about 30 students adjoins the hospital The charge for residence is £8 8*s* , £7 7*s* , and £6 6*s* per term, according to the position of the room. Breakfast, luncheon, and dinner are supplied in the College Hall at a very moderate charge

Fees —The Composition Fee for the entire curriculum is 135 guineas, or 145 guineas if paid in three instalments The fee for the Dental Curriculum is 54 guineas, or 60 guineas if paid in two instalments Students who have completed the study of Anatomy and Physiology or passed the London Preliminary Scientific M B Examination are received on special terms

The following appointments at the Infirmary are annually open to students (for some of them, however, a registered legal qualification is required) - Non resident senior anæsthetist £50, 5 anæsthetists, £25, pathological curator, £120 Resident medical officer, £100, surgical officer, £100, casualty officer, £100, obstetric, £50, ophthalmic, £50 These appointments are made annually and holders are eligible for re-election Resident medical officer to the Ida Hospital, for six months, honorarium £25 Six house physicians, for six months, 4 house surgeons, for 12 months, 24 physicians' clerks, for six months, 24 surgeons' dressers, for six months, 16 ophthalmic and aural surgeons' dressers, for three months, 12 gynæcological ward clerks, for three months, 16 gynæcological out-patient clerks, for three months, 24 maternity clerks, for one month, 24 assistant physicians' clerks, for three months, 8 dermatological clerks, for three months, 8 laryngological clerks, for three months, 24 assistant surgeons' dressers, for three months, 8 assistant ophthalmic surgeons' dressers for three months, 24 dressers in the casualty room, for three months, 32 post mortem room clerks, for three months, 8 laboratory assistants, for three months

There are appointments open to students in other medical institutions in the town and also in the West Riding (Lunatic) Asylum

UNIVERSITY COLLEGE, LIVERPOOL (VICTORIA UNIVERSITY) MEDICAL FACULTY —*Buildings* —The work of reconstruction of the Medical School buildings has been continued during the past two years by the erection of a new Dissecting Room and Anatomical Museum, which were opened last October The Dissecting Room is on the upper floor and measures 70 by 40 feet. It is well lighted from the north and east and provides adequate accommodation for the study of Practical Anatomy The Museum occupies the space below the Dissecting Room it is provided with a gallery on each side and gives ample room for the collections of human anatomy and of dental anatomy The excellent series of models dissections and preparations can now be properly displayed for the use of students More adequate provision has also been made for the departments of Surgery Midwifery and Materia Medica The work of completion of the school buildings is now in progress and when completed the building will form a block completing one side of the College quadrangle and connecting the dissecting room block just compl ted with the Thompson Yates Laboratories of Physiology and Pathology recently erected A new block is also being added to the Thompson Yates Laboratories to provide accommodation for study and research in Pathology and for the School of Tropical Medicine. Handsome and commodious Laboratories Lecture-rooms and Museum of Botany have been acquired this year by the gift of Mr W P Hartley and new Laboratories for Physics are at present in course of construction

---

* No returns

Chairs —A new Chair of Bio-Chemistry has been founded this year by the generosity of Mr William Johnston

Royal Infirmary —The Royal Infirmary which adjoins the School contains 300 beds with 40 special beds for the treatment of Diseases of Women The Lying in Eye and Ear Women s Children s Dental and Skin Hospitals are in the immediate vicinity and their practice is open to the students of the Medical Faculty

Fees —The composition fees are —£24 15*s* for Preliminary Scientific Classes £60 for the Medical Classes required for the Victoria, London and other University degrees and £70 for all the classes required for the diplomas of the Conjoint Boards The medical composition fees are payable in two instalments at intervals of 12 months The fee for hospital attendance at the Royal Infirmary is 40 guineas, also payable in two annual instalments

Appointments —Three house surgeons, three house physicians and one external house surgeon to the Thornton Wards are appointed for six months after (if necessary) competitive examination Clinical clerks for each physician dressers for each surgeon and clerks to the Thornton Wards for Diseases of Women are appointed every three months Post-mortem clerks are appointed for six weeks all students are required to perform this duty before the schedule for the Final Examination is signed.

Fellowships and Scholarships —Fellowships scholarships and prizes of over £700 are awarded annually (*a*) A Holt Fellowship in Pathology and Surgery of the value of £100 for one year is awarded annually by the medical faculty to a senior student possessing a medical qualification The successful candidate is required to devote a year to tutorial work and investigation in the pathological department (*b*) A Holt Fellowship in Physiology is awarded under similar conditions of the value of £100 for one year (*c*) A Robert Gee Fellowship in Anatomy awarded under similar conditions also of the value of £100 for one year (*d*) An Alexander Fellowship for Research in Pathology of the annual value of £100 renewable (*e*) A Johnston Colonial Fellowship in Pathology and Bacteriology (£100 a year renewable) (*f*) A John W Garrett International Fellowship in Physiology and Pathology (£100 a year renewable) (*g*) An Ethel Boyce Fellowship in Gynæcological Pathology (£100 a year renewable) (*h*) Two Lyon-Jones Scholarships of the value of £21 each for two years are awarded annually—a junior scholarship open at the end of the first year of study to Victoria University students in the subjects of the First M B Examinations, and a senior scholarship, open to all students in the school at the end of the second or third year of study on the subjects of Anatomy Physiology and Therapeutics (*i*) The Derby Exhibition of £15 for one year is awarded in Clinical Medicine and Surgery in alternate years Student may compete in their fourth and fifth years In 1903 the subject will be Clinical Medicine (*j*) The Torr Gold Medal in Anatomy and the George Holt medal in Physiology the Kanthack Medal in Pathology the Robert Gee Book Prize of the value of £5 5*s* for Children s Diseases and numerous Class Prizes are awarded annually

Entrance Scholarships —Four Robert Gee Entrance Scholarships of the value each of £25 for one year are offered annually for competition The holder is required to take out the Science Course for the University Degree in Medicine.

Communications should be addressed to the Dean Professor Paterson, M D University College Liverpool

---

Medical Department of Owens College (Victoria University) —This medical school is located in a large building which forms a part of Owens College. It is provided with large dissecting rooms, physiological laboratories, private laboratories, and work rooms, besides lecture-rooms, a museum, and a library In order to give the fullest possible opportunities for teaching and investigation in the departments of Anatomy Physiology Pathology and Materia Medica, a large extension of the school buildings was made in 1895 The greater part of the new buildings is devoted to the departments of physiology, pathology toxicology anatomy and public health The physiological department occupies more than half of the new buildings, and includes a large lecture theatre, accommodating 350 students, with preparation and diagram rooms adjacent to it, and a research laboratory fitted with the necessary apparatus for the use of advanced students, research scholars, or practitioners of medicine undertaking the investigation of some special subject. In the new pathological laboratories ample provision is made for the teaching of pathology and bacteriology and for the prosecution of original research In the toxicological department there is a large laboratory capable of accommodating 50 students, lighted from both sides and also from the roof, completely equipped with all that is necessary for the practical teaching of toxicology also a small laboratory for private research, containing the apparatus and fittings necessary for investigations in toxicological chemistry In the public health department suitable laboratory accommodation is provided for the study of sanitary chemistry physics and practical bacteriology in the departments of chemistry and physics and in that of pathology A large room is provided in the new buildings for a museum of apparatus models plans and other sanitary appliances for the practical instruction of the students, together with a special library of works on State medicine, hygiene, vital statistics and sanitary engineering In addition, a large lecture theatre for general purposes accommodating 250 students, has been provided and the existing accommodation for students is supplemented by the provision of a larger common room The more strictly practical departments of medical study are taught partly in the Medical School and partly in the Royal Infirmary as well as in a fever hospital a lunatic asylum and a convalescent home Medical and Surgical Clinical Classes are conducted in the Infirmary and separate instruction is afforded in the elements of Medical and Surgical Physical Diagnosis, in Obstetric Medicine Ophthalmic Surgery and Pathological Anatomy by the different members of the staff of the Medical School and Infirmary The following entrance scholarships are offered for award to persons of either sex proposing to enter a medical course of study at the College —Seaton —One of £40 tenable for two years Subjects Greek and Latin Translation at sight, and Prose Composition Credit given for knowledge of Mathematics (Geometry and Algebra) Elements of English Language Literature and History; French and German Rogers —One of £40 tenable for two years Subjects as in Seaton Dalton —Two of £60 tenable for two years Subjects Geometry (Euclid I —IV and VI, or the subjects thereof) Algebra (as far as the Binomial Theorem inclusive) Plane Trigonometry (to Solution of Triangles) Elementary Analytical Geometry; Conic Sections. Credit given for knowledge of Classics Elements of English Language, Literature and History French and German Cartwright —£35 per annum, tenable for three years Subjects as in Dalton Hulme —£35, tenable for three years. Subjects English Language (Grammatical Structure and Outlines of its History) English Literature (an essay on some subject of English literature) and Modern History (Outlines of English History and Geography) with at least two of the following Latin (Translation at sight, Grammar and Easy Composition); Greek (ditto) French (ditto) German (ditto) Credit given for knowledge of Mathematics (Geometry and Algebra) Dora Muir —£25 per annum tenable for three years (open to women only) Candidates may select such of the subjects as they desire from amongst those set for the other Entrance Scholarships James Gaskill —£35, tenable for two years Subject

Mathematics, Geometry (the substance of Euclid I —IV and VI), Algebra (as far as the Binomial Theorem, inclusive), Plane Trigonometry (to Solution of Triangles), Elementary Mechanics, Chemistry Credit given for knowledge of Classics, Elements of English Language, Literature, and History, and French and German Manchester Grammar School —£18 per annum, tenable for three years The examinations for all these scholarships are held in the month of May Kay Shuttleworth (Sir James Phillips) —£30 per annum, tenable for three years Subjects Mathematics, Elementary Mechanics, Chemistry Dauntesey Medical Scholarships —Two Scholarships of £35 each are open to all students preparing for a medical course who shall not have attended lectures or Laboratory courses on human anatomy or physiology, or a purely medical or surgical course in the Owens College or any other Medical School in the United Kingdom Candidates will be examined in Zoology, Botany, and Chemistry Medals are awarded on the results of the various class examinations at the end of each session A Platt Physiological Scholarship of £50 a year for two years is offered annually to the competition of persons whether previously students of the College or not. Two Platt Exhibitions, of the value of £15 each, to be competed for by first and second year students in the class of Physiology, and a Sidney Renshaw Exhibition in Physiology of the value of £15 to be competed for by second year students in Physiology A Professor Tom Jones Memorial Exhibition of the value of £25 a Dumville Surgical Prize of £15, a Turner Medical Scholarship of £20, and a John Henry Agnew Scholarship in Diseases of Children of £30 are offered annually for competition A Professor Tom Jones Memorial Scholarship of £100 is awarded triennially, a Bradley Memorial Scholarship in Clinical Surgery of the value of £20 and Medical and Surgical Clinical Prizes, each of the value of 6 guineas, are open to competition each year for the best reports (with comments) of cases which have occurred in the wards of the infirmary *The session commences on Oct 1st*

Manchester Royal Infirmary (292 beds) — Consulting Physicians Drs Frank Renaud and Henry Simpson Consulting Surgeons Messrs Walter Whitehead and James Hardie Physicians Drs J Dreschfeld, Graham Steell, Thomas Harris, and J S Bury Assistant Physicians Drs A T Wilkinson, Ernest S Reynolds, and R T Williamson Consulting Obstetric Physician Dr Lloyd Roberts Gynæcological Surgeon Dr Archibald Donald Surgeons Messrs F A Southam, G A Wright, William Thorburn, and Joseph Collier Assistant Surgeons Messrs J E Platt, W P Montgomery, and J W Smith Consulting Ophthalmic Surgeon Dr D Little Ophthalmic Surgeon Dr Hill Griffith Aural Surgeon Dr William Milligan Consulting Dental Surgeon Mr G W Smith Dental Surgeon Mr W A Hooton Pathological Registrar Dr A E Finney Medical Registrar Dr F C Moore Surgical Registrar Mr E D Telford Director of the Clinical Laboratory Dr W E Fothergill Assistant Director of the Clinical Laboratory Dr C H Melland Administrators of Anæsthetics Mr Alexander Wilson and Mr W J S Bythell Assistant Medical Officer for Out-patients Dr W R Matthews Assistant Surgical Officer for Out patients Mr G A Jelly Medical Officer for Home Patients Dr A C Sturrock. General Superintendent and Secretary Mr W L Saunder The Winter Session commences Oct 1st

The Royal Hospital, Portsmouth (*founded* 1847) — The number of beds is 150 During the year 1901 there were 1334 in patients and 9686 out-patients Physicians Dr C C Claremont and Dr John Phillips Surgeons Dr J Ward Cousins, Dr A Lloyd Owen and Mr Henry Rundle Assistant Physicians Dr D P McEldowney, Dr J Leon, and Dr L Cole Baker Assistant Surgeons Mr C P Childs Mr A B Wright, and Mr J A M Forde House Surgeon Mr N C Beaumont Assistant House Surgeon Mr G W Stone The hospital is a preparatory School of Medicine and Surgery, the attendance of pupils at this Hospital is recognised by the Examining Boards

University College, Sheffield—Department of Medicine.—The department of Medicine is now fully equipped with the most modern appliances in every part in this respect will compare favourably with similar tions elsewhere The Anatomical Department con- in addition to a spacious dissecting room, a large lecture theatre and an excellent museum of dissections, &c The Favell Laboratory of Physiology is elaborately equipped The department consists of a lecture theatre with lantern for demonstration purposes, and the laboratory is fitted with the most recent improvements Each student has his own bench, with gas, water, electric light, and the requisite set of apparatus The Pathology department is at present in a separate temporary building It contains a large museum of pathological specimens, student's laboratory, lecture room with lantern for demonstrations, also bacteriological and pathological laboratories The courses of instruction for the D P H examinations are recognised by the Royal College of Surgeons and Cambridge University The opportunities for clinical work in connexion with the Medical Department are exceptionally good For general clinical material the Royal Infirmary and the Royal Hospital offer unlimited supplies, both medical and surgical The Royal Infirmary contains 240 beds with special Ophthalmic and Dermatological departments The new operating theatre has been recently fitted with all the most modern improvements and is one of the finest in the kingdom The post mortem department has also been recently improved and contains all the requisites for clinical and pathological research The Royal Hospital, which has been entirely rebuilt during the last few years and is planned with all the latest improvements, contains 150 beds and has special ophthalmic wards There are also special out patient departments for diseases of the skin, nose and ear, eye, throat, and mental diseases At both these institutions clinical clerkships and dresserships, casualty and ophthalmic dresserships and post-mortem clerkships, are allotted each three months Clinical lectures are delivered each week during the winter months by members of the staffs, and daily systematic teaching is given in the wards and out-patient rooms at stated times By a joint arrangement students taking out hospital practice are able for the single fee to attend the practice of either or both of the institutions as they choose Fees Perpetual hospital practice £45 in one payment, or £26 on commencing hospital practice, and £22 12 months later For shorter periods the fees are at the rate of £2 2*s* per month Composition fee for lectures and practical courses, £63, or in two instalments £36 15*s* at commencement of medical study and £31 10*s* at the beginning of the second year For practical midwifery and disease of women students attend the Jessop Hospital for Women, which has recently been considerably enlarged and extended, for infectious diseases the City Fever Hospitals, and for mental diseases the South Yorks Asylum Arrangements are also being made for the systematic teaching of anæsthetics in accordance with the new regulations For all these special courses separate fees are required, which are not included in the composition or perpetual hospital fees In connexion with the College there is now a complete dental department, which is fully recognised by the various examining bodies, and students are able to get their full curriculum here The practical work is done at the dental department of the Sheffield Royal Hospital, where, in addition to the fully-equipped out-patient dental rooms, there has recently been added a very complete practical dental mechanical room and laboratory fitted with electric light and every modern convenience Each student has his own bench and fittings provided

Prizes, &c —An entrance scholarship of the value of £110 is awarded annually to the best candidate (if of sufficient merit) in Mathematics, Elementary Physics, Inorganic Chemistry, Latin, and English Prizes for Clinical Medicine and Surgery of 10 guineas are offered by the Clinical Committee Kaye Scholarship (being the interest on £900) for second-year students native of Sheffield is awarded annually under certain regulations Simon prize £10, given annually in pathology Prizes in books and certificates are awarded annually

Jessop Hospital for Women, Gell-street, Sheffield — The hospital is devoted to *Diseases Peculiar to Women* There is also an Obstetric Department for the admission of a small number of cases A staff of midwives connected with the hospital attend lying in women at their own homes, and, in case of need, are assisted by the members of the medical staff Out-patients are attended daily Students can attend the practice of the hospital and be supplied with cases of midwifery Communications should be addressed to the Secretary, York Chambers, York street, Sheffield.

Royal Devon and Exeter Hospital, Exeter —Medical and Surgical Staff Consulting Physician Dr Drake Physicians: Drs H Davy and William Gordon Consulting Surgeons Messrs. A J Cumming T W Caird, and James Bankart Surgeons Messrs J D Harris E. J Domville, Charles E Bell, and A C. Roper House Surgeon Mr P H. Stirk Assistant House Surgeon Mr W Hudson Marsden Junior Assistant House Surgeon Mr Norman E Gibbs The hospital contains 214 beds (including special children s wards) and has a good library museum, dissecting room, and post mortem room Attendance on the practice of this hospital qualifies for all the examining boards Arrangements can be made by which students can attend Midwifery on application to the House Surgeon There is also a Private Nursing Staff attached to the Hospital For *particulars as to fees &c., apply to the Matron* A new wing was added in 1897

West of England Eye Infirmary Exeter —Physician Dr William Gordon. Surgical Staff Messrs Bankart and Tosswill Assistant Surgeon and Registrar Mr Roper Secretary Mr Ernest W Toby The infirmary contains 64 beds Students of the Exeter Hospital can attend the practice of the Eye Infirmary Patients for the year ending Michaelmas, 1901, 2637 Total number of patients since the opening of the Infirmary in 1808, 102,826 Days of admission Mondays, Tuesdays, and Fridays, at 11 A M

Kent and Canterbury General Hospital.—Opened for the reception of patients April 26th, 1793 60 097 in patients and 105 004 out-patients have been admitted since the hospital was opened The hospital contains 104 beds Pupils of the staff are admitted to the practice of the hospital and have the use of the library of the East Kent and Canterbury Medical Society for £7 7*s* Operation day Thursday 11 A.M Physician Dr Henry Alex. Gogarty Consulting Surgeons Mr James Reid and Mr Frank Wacher Surgeons Messrs. T Whitehead Reid, J Greasley Sidney Wacher and Mr Z. Prentice Dentist Mr R S N Faro House Surgeon Mr R N Phillips Assistant House Surgeon Mr W H Duncan Secretary Mr Arthur J Lancaster Over 700 in patients, 2000 out-patients and casualties, and 500 dental cases are attended in a year

Royal Infirmary Liverpool. — The buildings of the *new Royal Infirmary* were completed and occupied as recently as 1890 They stand on the old site, adjacent to the College, but enlarged by the purchase of a fine frontage in Pembroke-place and with the Nurses Home are spread over some four acres of ground. Externally they form a handsome and imposing group of buildings Every available open air space has been taken advantage of to secure good airing grounds for the patients, and the beauty of the buildings has been not a little enhanced by the numerous balconies, colonnades, and flat roofs adapted to the same purpose for both patients and resident staff Internally no point in modern sanitary science has been omitted. There are 295 beds exclusive of the Lock Hospital. The wards—some parallelograms some circular—have walls of glazed bricks and floors of waxed oak blocks laid on an iron and cement substratum Four operating theatres and a clinical lecture theatre have been provided the operating theatres being of the latest pattern and fulfilling all the most modern requirements of surgery There is an electrical room and provision for special kinds of baths The out patient department comprises rooms for the treatment and study of minor medical and surgical maladies, for diseases of the eye, skin, larynx, nose, and teeth, as well as a gynæcological department. There is also a Lock Hospital. A room has been allotted to the clinical tutors, in which bacteriological investigations are made, whilst each physician and surgeon has a private room in connexion with his wards where his clerks and dressers may write up and tabulate cases and investigate morbid products The pathological department which is daily becoming of more importance in medical education, has had much pains expended upon it, so as to give proper facilities for the study of morbid anatomy It is hoped that the facilities for clinical work will be such as not merely to enable the present students to learn the practical parts of their profession thoroughly but to attract students from over crowded institutions where the number of pupils is far in excess of the opportunities for the bedside study of disease There are eight house physicians and surgeons and two casualty officers (one resident) who are selected every six months from amongst the qualified students of the school. In no hospital in the country is the resident staff so *comfortably lodged* Each is provided with a bedroom and a private sitting room in addition to the music-room and dining room where all meet in common, a Students Club Room is also set aside for their exclusive use Dr Bradshaw Secretary of the Medical Board 51, Rodney street. Liverpool.

Staff —Consulting Physicians: Dr Waters, Dr Davidson, and Dr Glynn Physicians Dr Caton, Dr Barr and Dr Bradshaw Assistant Physicians Dr Abram and Dr Buchanan Consulting Surgeons Mr Hakes and Mr Bickersteth. Surgeons Sir W M Banks Mr R. Parker and Mr F T Paul. Gynæcological Surgeon Dr Grimsdale Assistant Surgeons Mr R. A Bickersteth Mr G G Hamilton and Mr W T Thomas Oculist Mr. Bickerton Laryngologist Dr Hunt Dermatologist Dr L Roberts Dental Surgeon Mr Phillips. Pathologist Dr Ernest Glynn. Chloroformists: Mr Fingland and Mr Bailey Lock Department—Surgeon Mr Bernard

Liverpool Royal Southern Hospital.—(Clinical Schools) — Honorary Consulting Physician Dr John Cameron Honorary Consulting Surgeon Mr Robert Hamilton Honorary Physicians: Dr W Carter Dr W Williams, and Dr C J Macalister Honorary Surgeons Mr Wm Alexander Mr Robert Jones and Mr Geo P Newbolt Honorary Consulting Physician for Tropical Diseases Major Ronald Ross Honorary Dermatologist Mr F H Barendt. Honorary Consulting Ophthalmic Surgeon: Mr R. Williams. Honorary Consulting Aural Surgeon Mr C. G Lee. Honorary Consulting Laryngologist: Mr W Permewan Honorary Medical Officer x Rays Department Mr C Thurstan Holland Pathologist Dr Lyn Dimond Honorary Anæsthetists Dr J G Martin and Dr R. Jackson. Honorary Dental Surgeon Mr J Royston. House Surgeon Dr J W Wrightson Junior House Surgeons Dr Macrae Aitken and Dr T R W Armour The hospital is situated within convenient distance of the School of Medicine and contains 200 beds There are special wards for accidents and Diseases of Children and there are also beds appropriated to the Diseases of Women. Clinical teaching is given in the hospital and arrangements have been made to render it both thorough and systematic. The members of the staff visit the wards daily and clinical lectures are given every week *Tutorial classes are also held each day* at which the junior students are instructed in the methods of diagnosis and the seniors are prepared for their final examinations. The pathological department has a good laboratory attached in which the students receive practical instruction Recently a bacteriological laboratory has been added, where students are able to obtain a practical knowledge of bacteriology in relation to medicine In addition to the usual clinical and post-mortem clerkships, which are open to all students, the resident post of Ambulance Officer is awarded every three months to the student whom the board may consider most suited to hold it. A Scholarship of £20 is competed for annually which has attached to it some clinical and pathological duties and three prizes of £5 each are yearly offered for the best series of clinical reports Fees Perpetual £26 5*s*, one year £10 10*s* six months £7 7*s* three months £4 4*s* A limited number of resident pupils can be received. Terms (exclusive of fees for Hospital Practice) £15 15*s* per quarter The practice of the hospital is recognised by all examining bodies. For further particulars apply to the Dean Mr George P Newbolt, 42, Catharine-street, Liverpool.

Liverpool Northern Hospital.—The new hospital, under the title of the David Lewis Northern Hospital is now open *and accommodation provided* for 120 patients Clinical instruction at this hospital is recognised by the English Conjoint Board the Victoria University and other examining bodies. There is a fully-equipped Clinical Laboratory and a special department devoted to the light treatment and x ray work. Instruction is given daily by the physicians and surgeons during the winter and summer sessions. Clinical clerkships and dresserships are open to those who take out the practice of the hospital without additional fees Special arrangements are made for graduates desiring to undertake clinical research. Consulting Surgeon Mr W Macfie Campbell and Mr Chauncey Puzey Physicians Dr T Bushby and Dr W B Warrington Surgeons: Mr Damer Harrisson, Mr R W Murray and Mr Keith Monsarrat. Fees for hospital attendance Perpetual £26 5*s* one year £10 10*s* six months £7 7*s* three months £4 4, Practical Pharmacy £2 2*s* Students can enter to the medical or the surgical practice separately on payment of half the above fees Arrangements can be made for a limited number of resident pupils

Norfolk and Norwich Hospital (220 beds) —Non-resident Pupils admitted Fees For three months, £3 3s , for six months, £5 5s , as permanent pupil, £8 8s Consulting Physicians Sir P Eade, M D , and Sir Frederic Bateman, M D Consulting Surgeons Mr W Cadge and Dr Beverley Physicians Dr Barton, Dr Burton-Fanning, and Dr Long Surgeons Mr Williams, Mr H S Robinson, and Mr S H Burton Assistant Surgeons Mr D D Day and Mr H A. Ballance Dental Surgeon Mr H F White House Surgeon Mr L E Hughes House Physician Mr S G Champion, M D Secretary Mr F G Hazell

Northampton General Infirmary (established 1743 , rebuilt 1793) —The number of beds is 163 Out-pupils are received and have every opportunity of acquiring a practical knowledge of their profession Instruction is also given in Anatomy and Materia Medica and Practical Pharmacy Non resident pupils are taken at a fee of £10 10s

North Staffordshire Infirmary and Eye Hospital Hartshill, Stoke on Trent —The New Infirmary, opened in 1869 is built on the pavilion plan, has accommodation for over 200 patients, including Children's wards, special Ovarian wards, and a special department for the treatment of Diseases of the Eye In patients last year, 2047 , out-patients, 11,791 The attendance of pupils at this infirmary is duly recognised by all the examining boards , and there are unusual facilities for acquiring a practical knowledge of the profession. Physicians Dr A M McAldowie and Dr S King Alcock. Surgeons Dr G Stokes Hatton and Dr Wheeton Hind Assistant Physicians Dr Hubert Nicholls and Mr John Russell. Assistant Surgeons Mr Reginald Alcock and Dr W C Allardice Ophthalmic Surgeon Mr Herbert H Folker Assistant Ophthalmic Surgeon Mr J F Arlidge Dental Surgeon Mr A Baines House Surgeon Mr C A S Ridout. House Physician Mr H Hartley Secretary and House Governor Mr Albert E Boyce, F I.S

Wolverhampton and Staffordshire General Hospital (founded 1845 , beds, 230) —A preparatory school of Medicine and Surgery The pupils have the advantage of seeing the whole of the practice of the physicians and surgeons and are trained in clinical work by the medical and surgical staff The attendance of pupils at this hospital is recognised by all the examining boards

Staff —Consulting Physician Dr W Millington. Consulting Surgeon Mr C A. Newnham Physicians Dr H Malet and Dr C A. MacMunn Surgeons Mr J O'B Kough, Mr W H. T Winter, Mr E Deanesly, and Mr A. H Hunt. Assistant Physician Dr J A. Codd. Assistant Surgeons Mr W F Cholmeley and Mr H Dent

Sussex County Hospital (190 beds) —During the year 1901, 2248 in-patients have been treated. The total number of out-patient attendances on the books during 1901 was 36,852 This hospital affords ample facilities for students, possessing a large out-patient department, a library, and a well appointed museum The hospital does not take resident pupils, but out-pupils may attend the practice of the hospital for any period not exceeding two years on payment in advance of such a fee, not exceeding 20 guineas, as the Committee of Management shall direct.

Staff —Physicians Dr W A. Hollis, Dr E Mackey, and Dr F F G Dill. Assistant Physicians Dr E Hobhouse, Dr E F Maynard, and Dr W Broadbent Consulting Surgeons Mr F A. Humphry and Mr H P Blaker Surgeons Mr W Furner, Mr T J Verrall, and Mr R. F Jowers Assistant Surgeons Mr F J Paley, Mr A. Buck, and Mr T H Ionides

Manchester Children's Hospital, Pendlebury and Gartside street —The hospital contains 168 beds and 24 in the Convalescent Home St Anne's on Sea. The medical staff visit the hospital daily at 10 A M Clinical instruction is given by the medical staff at the Hospital and Dispensary Out-patients are seen daily at 9 A M at the Dispensary, Gartside-street. Manchester Physicians Drs Ashby and Hutton Surgeon Mr W P Montgomery Hon Surgeons Mr G A Wright, Mr Joseph Collier, and Mr J Howson Ray Anæsthetist Mr W J S Bythell Honorary Aural Surgeon Mr F R Westmacott. Honorary Dental Surgeon Mr Barron J Rodway Resident Medical Officers Mr Wrigley and Mr Harper Medical Officer at the Dispensary Mr Tattersall During 1901 there were 1395 in-patients and 15 586 out-patients were under treatment the Dispensary

The Manchester Clinical Hospital for Women and Children Cheetham hill road, Manchester —The hospital is situated near the centre of the town and contains 70 beds Out-patients are seen daily at 9 30 A M and the wards are visited at 11 A M Secretary, Mr H Teague, 38, Barton arcade Manchester

Newcastle on-Tyne Infirmary for Diseases of the Eye —Staff Surgeons Mr A S Percival, M B , M A , and Mr H P Bennett, M B , C M Assistant Surgeon Andrew Messer, M B , B Sc Out-patients annually 4000 Instruction daily 11 to 1.

SCOTLAND

MEDICAL SCHOOLS WITH FULL CURRICULUM [1]

School of Medicine of the Royal Colleges, Edinburgh.—The number of students varies much in the classes and subjects It is within the limit to say that about 1300 students avail themselves each year of the opportunity of attending the school The lectures qualify for the University of Edinburgh and other Universities, the Royal Colleges of Physicians and Surgeons of Edinburgh, London, and Dublin, the Faculty of Physicians and Surgeons of Glasgow, and other Medical and Surgical and Public Boards

The anatomy rooms and laboratories will open on Wednesday, Oct 1st On Tuesday, Oct 14th, the lectures will commence

In accordance with the statutes of the University of Edinburgh one half of the qualifying classes required for graduation may be attended in this school, in addition to the class of Practical Materia Medica and the classes of Clinical Medicine and Clinical Surgery The regulations require that the fee for any class taken for graduation in Edinburgh shall be the same as that for the corresponding class in the University The whole education required for graduation at the University of London may be taken in this school

The appointment of Resident Physician to the wards in the Royal Infirmary under the care of the Ordinary Physicians is open to those members of their clinical class who have clerked in their wards for at least six months Six Residentships are appointed during the year for a period of six months each Resident Surgeons are also appointed by the Ordinary Surgeons to the Hospital In all respects the students are taught under regulations similar to those at the University of Edinburgh and the other Universities of Scotland, and they receive similar certificates at the close of each session Moreover, the University and College authorities in Edinburgh and the governing board of the school call upon each recognised lecturer to supply them at the close of each session with a statement giving the number of students attending the class, the number of lectures or prelections delivered during the session, the class examinations held, and the general mode of conducting the class The courses on special non qualifying subjects have for the last quarter of a century formed a marked feature of the school. Indeed, such medical subjects could be studied in Edinburgh only in this school until lately, when the University of Edinburgh appointed from the school lecturers on Diseases of the Eye, Insanity, and Diseases of Children to take charge of classes intra murally A list of the classes and lecturers will be found below Special courses of instruction for dental students and for women are also included in the curriculum of this school The classes of the school are conducted in several separate buildings, such as at Surgeons' Hall, Minto House, Nicolson square, and the New School, Bristo-street

Lecturers and fees —Winter Session Anatomy, Practical Anatomy and Demonstrations, Drs Ryland Whitaker and R J A Berry (£3 5s and £4 4s), Chemistry (Practical, &c), Mr King Mr Gemmell, and Mr Kerr *, Physiology (Institutes of Medicine), Dr Noël Paton (£3 5s), General Pathology &c , Drs Bruce, Russell, Shennan, and Stuart McDonald (£3 5s) , Biology, Mr A T Masterman and Miss Newbigin , Zoology, Mr Masterman and Miss Newbigin , Bacteriology, Dr Taylor Grant , Practice of Physic, Drs James Affleck, Bramwell, Gibson, Philip, Graham Brown, R A Fleming, and G Lovell Gulland (£3 5s), Surgery, Messrs Caird, Hodsdon, Thomson, Wallace, and Miles (£3 5s), Materia Medica, &c , Drs Craig † and W Wood (£3 5s) , Midwifery, &c , Drs Hart,

The minimum cost of the education in this School of Medicine for the Triple Qualification of Physician and Surgeon from the Royal Colleges of Physicians and Surgeons of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow including the fees for the Joint Examinations is about £115 payment of which is distributed over the period of study

Further particulars regarding the School also the calendar may be had on application to Mr R Y Ramsay, Secretary 24 Forrest road Edinburgh

---

Lectures £3 5s; Practical, £3 3s; Analytical £2 a month, or £5 for three months † Also in Summer Session. ‡ Also in Winter Session. § Practical, £3 3s; Analytical £2 a month or £5 for three months.

N.B.—Where two or more lecturers appear as teaching the same subjects their lectures are not conjoined but each gives an independent course.

ANDERSON'S COLLEGE MEDICAL SCHOOL, Glasgow —This medical school was founded in the year 1800 It has given thirteen professors to the University of Glasgow The following courses are given which qualify for all the licensing boards and for the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions) —In winter Anatomy Professor A. M Buchanan, M A., M D, Chemistry Professor J Robertson Watson, M A, Physics, Professor Peter Bennett, Botany, Professor B G Cormack M A B Sc. Zoology Professor Geo Bell Todd, M B, Physiology (vacant), Surgery Professor T Kennedy Dalziel, M B Practice of Medicine Professor R. S Thomson M D D Sc Diseases of Women, Professor John Edgar M A., B Sc. M D Materia Medica, Professor R. Barclay Ness M A M B Ophthalmic Medicine and Surgery T Spence Meighan, M D Aural Surgery J Galbraith Connal M B, Diseases of Throat and Nose John Macintyre M B In summer Anatomy, Practical Anatomy and Osteology Practical Chemistry Physics, Zoology Practical Materia Medica and Pharmacy Practical Physiology Operative Surgery Botany Ophthalmic Medicine and Surgery also Medical Jurisprudence (Professor Carstairs Douglas, B Sc M D) and Mental Diseases (Dr Carswell) and Aural Surgery The Chemical Laboratory is open daily from 10 to 6 The Dissecting room is open in winter from 9 A M to 6 P M and in summer from 6 A M to 6 P M The students are assisted in their dissections by the Professor and Demonstrators, by whom frequent examinations and demonstrations on the parts dissected are conducted The supply of subjects for dissection is ample, and students are consequently provided with parts as soon as they may be ready for them The Dissecting room is provided with a complete series of dissected specimens *mounted in plaster of Paris*, illustrating the anatomy of the human body Candidates for the Licence in Dental Surgery can obtain the full medical curriculum in Anatomy Chemistry Physiology Surgery Practice of Medicine and Materia Medica The courses special to Dentistry are conducted at the Glasgow Dental Hospital and School

The new buildings are situated in Dumbarton road immediately to the west of the entrance to the Western Infirmary within two minutes walk of it, and four minutes walk of the University Extensive accommodation is provided for Practical Anatomy Practical Chemistry Practical Physiology Practical Pharmacy and Operative Surgery There are also provided a large library and reading room and a students recreation room.

Fees—For each course of Lectures (Anatomy Ophthalmic Medicine and Surgery Aural Surgery Diseases of Throat and Nose and Mental Diseases excepted) first session, £2 2s second session (in Anderson's College), £1 1s, afterwards free For Practical Classes (except Anatomy)—viz. Chemistry Botany Zoology Physiology Pharmacy and Operative Surgery—first session £2 2s second session £2 2s Reduced joint fees in Zoology and in Botany for Lectures and Practical Class when taken in same summer session £3 3s for either course separately £2 2s Anatomy Class Fees: Winter first session (including Practical Anatomy) £4 4s second session (including Practical Anatomy) £4 4s; third session £2 2s To those who have had the necessary courses of Practical Anatomy the fee will be £1 1s Summer Lectures and Practical Anatomy £2 12s 6d Lectures alone £1 11s 6d Practical Anatomy alone, £1 1s Osteology and Practical Anatomy £2 12s 6d Osteology alone £1 11s 6d Students who have attended classes at other schools and who desire to pursue their studies at Anderson's College Medical School, will be admitted to such classes as they may have attended elsewhere at the reduced *fees* Ophthalmic Medicine and Surgery (including Hospital Practice) Aural Surgery Diseases of Throat and Nose and Mental Diseases £1 1s each course Matriculation Fees Winter 10s to those taking out two or more classes 5s. to those taking out only one class The fee of 10s represents a combined fee for the winter and summer session Summer 5s except to those who have paid a fee of 10s for the Winter Session

Western Infirmary—Fees For Hospital Attendance first year £10 10s. afterwards free For each Clinical Class in winter £3 3s in summer £2 2s After three such annual payments of £5 5s the fee for each Clinical Class will be £1 1s Pathology first course £3 2s second course £2 2s Vaccination fee £1 1s

Royal Infirmary —Fees Hospital Practice and Clinical Instruction, first year, £10 10*s* , second year, £10 10*s* , afterwards free Six months £6 6*s* , three months, £4 4*s* , Pathology, both courses, £4 4*s* Vaccination Fee, £1 1*s*

Attendance at the dispensaries of the Western and Royal Infirmaries is included in the hospital fee

Eye Infirmary —Fee Hospital Practice and Clinical Instruction, including Lectures at the college, six months, £1 1*s*

Maternity Hospital —Fee for six months, £2 2*s*

Fever Hospital —Fee, £1 1*s*

Hospital for Skin Diseases —Fee, £1 1*s*

Certificates of attendance on the lectures at Anderson's College Medical School are received by the Universities of London, Durham, Ireland, Edinburgh, and Glasgow (the latter two under certain conditions) , by the Royal Colleges of Physicians of London and Edinburgh , by the Royal Colleges of Surgeons, England, Edinburgh, and Ireland , by the Royal College of Physicians of Ireland , by the Faculty of Physicians and Surgeons of Glasgow , by the Society of Apothecaries, London , and by the Army, Navy, and East India Boards. Communications relating to the Medical School to be addressed to the Secretary of the Medical Faculty, Anderson's College Medical School, Dumbarton-road, Partick, Glasgow Communications relating to the Preliminary Examination in General Education to be addressed to Mr Alexander Mackay, LL D , Educational Institute Office, 40, Princes street, Edinburgh Communications relating to the Triple Qualification to be addressed to Mr Alexander Duncan, LL D , Faculty Hall, 242, St Vincent-street, Glasgow Communications relating to the Dental School to be addressed to Mr D M Alexander, 97, West Regent-street, Glasgow

The Kerr Bursary in Anatomy (value about £10) is open to students of the Junior Anatomy Class during Winter Session 1902-1903

ST MUNGO'S COLLEGE AND GLASGOW ROYAL INFIRMARY —This College was incorporated in 1889 The Glasgow Royal Infirmary was founded in 1791 The Faculty of Medicine of the College occupies new buildings erected for the purposes of a medical school, adjoining and communicating with the Royal Infirmary The Laboratories, Museums, and Lecture-rooms are equipped and adapted to modern scientific requirements Recent additions consist of Public Health, Practical Zoology, and Bacteriological Laboratories The Royal Infirmary, which is at the service of the College for the purpose of clinical and practical instruction, is one of the largest general and special hospitals in the kingdom It has nearly 600 beds, and will almost immediately have considerably over 600 It has special wards for Diseases Peculiar to Women, for Venereal Diseases, Erysipelas, Burns, and Diseases of the Throat and Nose At the Dispensary special advice and treatment are given in diseases of the Eye, Ear, Teeth, and Skin, Women, Throat and Nose, in addition to the large and varied number of ordinary medical and surgical cases—over 46 000 per annum—which in a great industrial centre daily require attention. Students of the College and Hospital get the benefit of dispensary experience free of charge. All appointments are open. There are five Physicians' and seven Surgeons' Assistants, who board in the hospital free of charge and act in the capacity of House Physicians and House Surgeons These appointments are made for six months and are open to gentlemen who have a legal qualification in Medicine or Surgery, and preference is given to the students of this College and Hospital Clerks and Dressers are appointed by the Physicians and Surgeons From the large number of cases of acute disease and accidents of varied character received into this hospital these appointments are very valuable In the Pathological Department assistants are also appointed The session will open with an address on Oct 16th at the College buildings

Ophthalmic Department —The Ophthalmic Institution in West Regent-street having been amalgamated with the Royal Infirmary the usefulness of this department is very much increased, and greater opportunities are afforded to students for the practical study of Diseases of the Eye Dr Ramsay, the ophthalmic surgeon, attends the Royal Infirmary every Monday, Wednesday, and Friday at 12 noon, and daily at the Institution in West Regent-street from 1 to 2 o'clock Students can attend both without payment of any additional fee Lectures are delivered twice a week during the winter session Fee for the course, £2 2*s*

Electrical Department —The new pavilion has been fully equipped with the most modern apparatus for the diagnosis and treatment of medical and surgical cases Consulting Medical Electrician John Macintyre, M B , F R S E Medical Electrician James Riddell, L R C P , &c Patients are seen from 9 to 11 A M daily

Psychological Medicine —Practical instruction is given in Woodilee Asylum, situated within a short distance of Glasgow and having accommodation for 850 patients Six resident clinical clerks are appointed annually These clerkships are open to students attending St Mungo's College

Clinical Instruction in Fevers —This class is conducted by Dr Johnston, Superintendent, at the city of Glasgow Fever Hospital, Ruchill, which has accommodation for 528 patients

The fee for each class is £2 2*s* , except for Anatomy, Winter Session, which is £4 4*s* , Pathology £4 4*s* , Zoology £4 4*s* , Botany £3 3*s* , Practical Physiology £3 3*s* , and for Physics, which is £2 4*s* 6d , and certain extra classes, for which the fee is £1 1*s* The hospital fee (including clinical lectures) is £21 for a perpetual ticket The classes in St Mungo's College and in the Glasgow Royal Infirmary are for male students exclusively The fees for all the lectures, including hospital attendance, necessary for candidates for the Diplomas of the English or Scotch Colleges of Physicians and Surgeons amount to £72 Further particulars can be obtained from a syllabus which can be obtained free on application to the Dean, 86, Castle-street, Glasgow

GLASGOW WESTERN MEDICAL SCHOOL —This School is situated in University-avenue, close to the University and Western Infirmary Lectures and Demonstrations are given on Chemistry, on Physics, on Zoology, on Anatomy, on Surgery, on Physiology, on Midwifery and Gynæcology, on Pathology, on Medicine, and on the Eye

Class Fees —For each course of Lectures the fee is £2 2*s* , or in some cases £1 1*s* There is no matriculation fee

QUEEN MARGARET COLLEGE, University of Glasgow — Queen Margaret College was founded in 1883 by the Glasgow Association for the Higher Education of Women (instituted in 1877), and handsome buildings and grounds near the University were presented to the College in 1884 by Mrs John Elder In 1890 a School of Medicine for women was added to its Arts Faculty In 1892, when the Universities Commissioners issued an ordinance empowering the Scottish University Courts to make provision for the instruction of women, the Council of the College and Mrs Elder transferred to the University the College, its buildings, grounds, and endowments, on condition that these should be devoted to the maintenance of University classes for women only The College then became the women's department of the University of Glasgow , its classes are taught by professors of the University and other lecturers appointed by the University Court, and it is governed by the University Court and Senate. The curriculum, regulations, and fees are the same as those of the male students, and the University degrees are open to women on the same conditions as to men They have access to the University Museum and can borrow books from the University Library, besides having a library of reference in Queen Margaret College The number of students enrolled in session 1901-1902 was 348, of whom 69 were studying medicine and the rest arts or science The School of Medicine is a special feature of the College and gives full preparation for the medical degrees of the University In July, 1894 for the first time in the history of any Scottish university, women students graduated in medicine at the "capping" in Glasgow University 70 women have now taken the degree of M B , C M or M B , Ch B of the University of Glasgow Excellent facilities for clinical work are given in the Royal Infirmary and other hospitals By a gift of £5000 granted for the purpose by the Bellahouston Trust the University Court was enabled to add to the College a large building for the study of Anatomy and Physiology, which was opened in October, 1895 The Arthur Scholarship is open every third year to students of first year , other Bursaries are open in Arts and Medicine , and by an ordinance of the Universities Commissioners women are admitted to certain University bursaries, scholarships, and fellowships A house of residence for the students of the College coming from a distance was opened by the Queen Margaret Hall Co , Limited, in October of 1894

UNIVERSITY COLLEGE, Dundee —This College is one of the constituent colleges of the University of St Andrews. The complete medical curriculum can be taken in Dundee For classes fees &c see under University of St Andrews.

ROYAL INFIRMARY Dundee —The Infirmary contains 300 beds, including special wards for the *Diseases of Women*, Children, Eye, Ear and Throat, and Lock cases There is also a Maternity-Department, in and out-door There were during last year 12 269 *out-patients* and 6723 home patients The Royal Infirmary offers exceptional facilities for practical work to students Appointments Four qualified Resident Medical Assistants are appointed every six months Clinical Clerks and Dressers are attached to the Physicians and Surgeons, and students are appointed as assistants in the Pathological Department. There are in *connexion with the clinical courses Tutorial Classes* in Medicine and Surgery Instruction is also given in Practical Pharmacy and Materia Medica and in Practical Dentistry Full information can be obtained from Dr Fraser Medical Superintendent

ROYAL ASYLUM Dundee —Lectures on Mental Diseases and clinical instruction in connexion with University College Dundee (University of St. Andrews) are given at the University College and at the Royal Asylum by Dr Rorie. There are two paid qualified Resident Assistants and two unpaid Resident *Clinical Assistants* The last Summer Session began on April 23rd 1902, and the course consisted of 12 Lectures at University College and 14 Clinical Lectures and Demonstrations at the Royal Asylum Present Medical Assistants Wm Tuach M B., Ch B and W L G Anderson M B Ch B Clinical Assistant [Vacant.] The next session will begin on April 22nd 1903

ABERDEEN ROYAL LUNATIC ASYLUM —Contains with hospital attached to main institution and Agricultural Branch, about 950 beds. Medical Superintendent Dr William Reid Assistant Physicians Dr H de M Alexander Dr Alexander Watt and Mr Reg A. Forster Clerk Treasurer and Factor Mr J B Findlay Clinical instruction is given to students during three months in summer

ABERDEEN ROYAL INFIRMARY — Contains 240 beds Consulting Physician Dr P Blaikie Smith Physicians Dr Angus Fraser Professor Finlay and Dr George M Edmond Assistant Physicians Drs John Gordon, A. H Lister, and Ashley W Mackintosh Consulting Surgeons Professor Alexander Ogston Drs J C. O Will and R J Garden Surgeons Drs J McK Booth J S. Riddell and John Marnoch Assistant Surgeons Drs W Sinclair, H M W Gray and John W Milne. Ophthalmic Surgeon Dr C. H. Usher Gynæcologist Professor W Stephenson Pathologist Professor David James Hamilton Assistant Pathologist Dr G M Duncan Dental Surgeon Dr J M P Crombie Anæsthetist Dr J J Y Dalgarno Assistant ditto: Dr W R Pirie Medical Electrician Dr J R Levack Clinical Registrar and Lecturer on *Diseases of the Skin* Dr J F Christie Medical Superintendent Dr Charles Angus Clerk and Treasurer and Factor for the Hospital Lands Mr John B Findlay

HOSPITALS AFFORDING FACILITIES FOR CLINICAL OBSERVATION

ROYAL INFIRMARY Edinburgh —Beds are set apart for clinical instruction by the professors of the University of Edinburgh Courses of Clinical Medicine and Surgery are also given by the ordinary physicians and surgeons. Special instruction is given in the medical department on Diseases of Women, Physical Diagnosis, and on Diseases of the Skin and in the surgical department on Diseases of the Eye the Ear the Larynx, and the Teeth Separate wards are devoted to Venereal Diseases, Diseases of Women, Diseases of the Eye, the Ear and the Skin, and also to cases of Incidental Delirium or Insanity Three wards are specially set apart for Clinical Instruction to Women Students Post mortem examinations are conducted in the anatomical *theatre by the pathologist and his assistants*, who also give practical instruction in Pathological Anatomy and Histology The *fees* for hospital attendance are as follows—viz Perpetual ticket in one payment, £12 annual ticket, £6 6*s* six months, £4 4*s* three months, £2 2*s* monthly £1 1*s* Separate payments amounting to £12 12*s* entitle the student to a perpetual ticket No fees are paid for any medical or surgical appointment The appointments are as follows —1 Resident physicians and surgeons are appointed and live in the house free of charge The appointment is for six months but may be renewed at the end of that *period by special* recommendation 2 Non resident house physicians and surgeons and clinical assistants are appointed *for six months* The appointment *may be renewed for a like period by special* recommendation 3. Clerks and *dressers* are appointed by the physicians and surgeons These appointments are open to all students and junior practitioners holding hospital tickets 4 Assistants in the Pathological Department are appointed by the pathologist

Staff Medical Department —Consulting Physicians Dr George W Balfour Dr Claud Muirhead and *Dr J O Affleck* Consulting Gynæcologist Dr J Halliday Croom Professors of Clinical Medicine *Dr T R Fraser, Dr W S Greenfield* and *Dr John Wyllie. Ordinary Physicians* and *Lecturers* on Clinical Medicine Dr Andrew Smart Dr *Alex James* Dr Byrom Bramwell and *Dr* Geo Gibson Gynæcologists Professor A R. Simpson and *Dr D Berry Hart*. Physician for Diseases of the Skin Dr Allan Jamieson Medical Electrician Dr Dawson Turner Assistant Physicians Dr Alex Bruce Dr R. W Philip *Dr William* Russell Dr Murdoch Brown Dr G Lovell Gulland Dr J J Graham Brown Dr Francis D Boyd and Dr A. Fleming Assistant Gynæcologists Dr A H. F Barbour Dr Milne Murray and Mr N T *Brewis* Assistant *Physician* for Diseases of the Skin Dr Norman Walker Assistant Medical Electrician Dr Hope Fowler Medical Registrar Dr A Lockhart Gillespie

Surgical Department —Consulting Surgeons Dr P H Watson Mr Joseph Bell Mr A G Miller and *Dr* P H Maclaren Consulting Dental Surgeon Dr John Smith. Consulting Ophthalmic Surgeon Dr Argyll Robertson Regius Professor of Clinical Surgery Mr Annandale Professor of Surgery Mr Chiene Ordinary Surgeons Dr C W MacGillivray Mr J M *Cotterill* and Mr C W Cathcart Ophthalmic Surgeons Mr George A. Berry and Dr George Mackay Surgeon to Ear and Throat Department Dr P MacBride Assistant Surgeons Mr F M Caird Mr Hodsdon Mr D Wallace Mr Alexis Thomson Mr Alexander Miles and Mr J W Dowden Assistant Ophthalmic Surgeons Dr William George Sym and Dr J V Paterson Assistant Surgeon to the Ear and Throat Department Dr R. M'Kenzie Johnston Dental Surgeon Mr William Guy Pathologist Dr Theodore Shennan Assistant *Pathologists Dr Stuart M'Donald* and *Dr* J M Beattie Surgical Registrar Dr Scott Carmichael Superintendent Colonel W P Warburton I M S (retired) M D C S I

ROYAL HOSPITAL FOR SICK CHILDREN Sciennes road Edinburgh *—This hospital, which has been recently built contains 120 beds and is fitted with every modern improvement A fully equipped out patient department (medical and surgical) is conducted daily in a building adjoining the hospital Systematic courses of instruction which qualify *for graduation in the Edinburgh University* and elsewhere are given from time to time through at the year by the staff. Students may enter at any time Full particulars can be obtained *from* the Registrar at the hospital

EYE EAR, AND THROAT INFIRMARY OF EDINBURGH 6 Cambridge-street, Lothian road —The Infirmary has been entirely re arranged and greatly improved by recent structural alterations and the electric light introduced also the electric power is used for illumination and cauterising purposes in all departments Clinical Lectures and Instruction are given in this institution, which is open at 1 o clock daily for outdoor patients for Eye Diseases Mondays Thursdays and Saturdays at 12 noon and Tuesdays and Fridays at 4 P M. for outdoor Ear Nose and Throat Patients Special Practical Ophthalmoscopic Classes by arrangement Patients whose diseases require operations or more than ordinary care are accommodated in the house Consulting Surgeon Dr Joseph Bell Surgeons Dr G Hunter Mackenzie, Dr William George Sym, Dr Logan Turner Dr Malcolm Farquharson Dr John Cumming and Dr J V Paterson Dental Surgeon Mr G W Watson Treasurer and Secretary Mr J P Watson, W S 13, Hill street

GLASGOW WESTERN INFIRMARY —This hospital adjoins the University of Glasgow Number of beds upwards of 420 Special wards are set apart for Diseases of Women and for Affections of the Skin. In the out patient department there are special clinics for Diseases of Women and for

---

* No return

Diseases of the Throat, Ear, and Teeth The Clinical Courses are given by the Physicians and Surgeons, each of whom conducts a separate class, and students require to enter their names at the beginning of the session for the class which they propose to attend. Special instruction is given to junior students by tutors or assistants, and clinical clerks and dressers are selected from the members of the class All the courses of clinical instruction are recognised by the University of Glasgow and the other boards in the kingdom In the Pathological Department the course is both systematic and practical, also post-graduate courses, and extends through the winter and following summer, these are likewise recognised by the University for graduation Ten resident assistants are appointed annually, without salary, from those who have completed their course The fee for the hospital practice, including the various courses of clinical instruction, is 20 guineas in one payment, or in two equal instalments for the first and second year, for six months, 7 guineas, and for three months, 4 guineas

Staff —Honorary Consulting Physicians Dr G P Tennant and Sir W T Gairdner, K.C B Visiting Physicians Professor T McCall Anderson, Dr J Finlayson, Dr S Gemmell, and Dr R. Stockman Physicians for Diseases of Women Professor M. Cameron and Dr W L. Reid Assistant Physicians Dr J Alexander, Dr W G Dun, Dr R S Thomson, and Dr R B Ness Dispensary Physicians Dr W R Jack, Dr H. E Jones, Dr Hugh Galt Dr Jas Carslaw, Dr John M Cowan, and Dr Alfred Webster Dispensary Physicians for Diseases of Women Dr R. Kirk, Dr J M M. Kerr, and Dr E H L Oliphant Honorary Consulting Ophthalmic Surgeon Dr T Reid Honorary Consulting Surgeon Dr Geo Buchanan Visiting Surgeons Professor Sir Hector C Cameron, Professor Sir W Macewen, Professor J C Renton, Dr G T Beatson, C B, and Dr T K. Dalziel Assistant Surgeons Dr J H. Nicoll, Dr D Macartney, Dr R Kennedy, Dr A. A Young, and Dr G B Buchanan Dispensary Surgeons Dr J Morton, Dr G H. Edington, and Dr F Macrae Extra Dispensary Physicians Dr John S M'Kendrick, Dr Robt Fullerton, and Dr I Campbell M'Clure Dispensary Aural Surgeon Dr T Barr Dispensary Throat Surgeon Dr J W Downie Vaccinator Dr J W Nicol Pathologist Professor R. Muir Assistant Pathologist A R Ferguson Dental Surgeon W D Woodburn Medical Superintendent Dr D J Mackintosh Visiting Surgeons Professor Sir Hector C Cameron, Professor Sir W Macewen, Dr J C Renton, Dr G T Beatson, C B, and Dr T Kennedy Dalziel Dispensary Surgeons Dr J Morton, Dr G H Edington, and Dr Farquhar Macrae

Royal Hospital for Sick Children, Glasgow, situated at Garnethill —This Hospital was opened in December 1882, and is now available to medical students for clinical instruction in the diseases peculiar to childhood The hospital includes 80 beds for non infectious cases only A specially designed Dispensary, or Out-patient Department was opened in October, 1888. Classes are formed both at Hospital and Dispensary at the beginning of the University session in October Students may be enrolled at any time Fee £1 1s per annum, admitting to both Hospital and Dispensary Particulars on applying to the House Surgeon, 45, Scott-street, Garnethill, Glasgow

Glasgow Ophthalmic Institution, 126, West Regent street (31 beds and four cots) —Clinical and systematic course of lectures for students during the winter and summer sessions In patients, 832, out- or dispensary patients, 4036 Operations on Wednesdays and Saturdays Honorary Consulting Surgeon D N Knox, M B, C M, F F P S G Surgeon A Maitland Ramsay, M D Assistant Surgeon John Rowan, M B, C M Junior Assistant Surgeons Hugh Walker, M B, C M, H Wright Thomson, M B, C M, and John Gilchrist, M B, C M Pathologist Hugh Walker, M B, C M Electrician John Gilchrist, M B, C M House Surgeons Peter McFadyen, M B, Ch B This institution is the Ophthalmic Department of the Royal Infirmary A post graduate course is given by Dr Ramsay and assistants during November and December Clinical instruction is given in the summer session to students of Queen Margaret College and in winter to students of St Mungo's College and to all who take the class

Glasgow Eye Infirmary, Berkeley street and Charlotte-street.—This institution, the largest of its kind in Scotland was founded in 1824 The Infirmary now consists of two large buildings—that in Berkeley street being occupied as the Infirmary proper, and that in Charlotte-street (new buildings opened June, 1894) as a dispensary The Infirmary is devoted exclusively to the treatment of Diseases of the Eye, and is intended primarily to provide treatment, and, when necessary, board and lodging, for those who are unable to do so for themselves The average number of new patients for the last ten years has been 16,855 3, and the total number of cases treated in 1901 was 21 549 The Medical Staff is as follows —Surgeons Thomas S Meighan, M D, A Freeland Fergus, M D Andrew Wilson, M B C M, James Hinshelwood, M A, M D, Leslie Buchanan, M D, W Ernest Thomson, M A, M D, Assistant Surgeons A Lewis M'Millan, M D, Henry L G Leask, M D, W Cochrane Murray, M.B, C M, Brownlow Riddell, M D, James D Cochran, M B, Ch B, Arthur J Ballantyne, M B, Ch B Pathologist Leslie Buchanan, M D House Surgeon W B Inglis Pollock M B Ch B Assistant House Surgeon John Strathern, M B, Ch B

Regulations as to Attendance of Students —(1) Gentlemen may attend as students on payment to the treasurer of the following fees —For six months £1 1s, twelve months £2 2s (2) All students when duly entered in the Infirmary Register may attend the clinical instruction of any or every member of the medical staff on production of their tickets The days on which the surgeons respectively attend to receive patients may be ascertained at the Infirmary Students have the privilege of being present in the Dispensaries at such hours as are arranged They may enter the wards along with the surgeon whose clinique they are attending when he visits his patients They may also be present at operations under the sanction of the surgeon operating, but no student may enter the wards or operating-room except under the aforesaid regulation Students may be allowed the use of the journals and case-books for examination on applying to the House Surgeon The wards and dispensary are recognised by the University of Glasgow for the purpose of instruction in ophthalmology for graduation in medicine Secretary and acting Treasurer William George Black, 88, West Regent-street Medical session begins in April

IRISH SCHOOLS OF MEDICINE[1]

Royal College of Surgeons in Ireland —See p 627

Queen's College School of Medicine, Belfast —Ten Junior Scholarships have been founded in the Faculty of Medicine of the annual value of £20 each Two are tenable by matriculated students, of the first, second, third, fourth, and fifth years of their course respectively The examinations for Scholarships take place at the commencement of the session Class Prizes are awarded at examinations which take place at the close of the session. The Exhibitions, &c, of the Royal University of Ireland are also open to students Lectures in Medicine at Queen's College, Belfast will commence on Oct 21st and end on March 22nd The Summer Medical Classes will begin on May 4th, except Botany, which begins on April 1st The new Chemical Buildings contain, in addition to a large class room for elementary practical chemistry, laboratories for qualitative and quantitative analysis, rooms for water and gas analysis, dark room for photographic purposes, balance room, &c, provided with all modern appliances Special facilities are given to those who wish to pursue original research The Anatomical Department contains a large and well lighted dissecting room, a lecture room, a professor's and demonstrator's room, a bone room, and a laboratory for microscopic and photographic work The medical museum is in the same building The physiological department (opened in 1896) comprises (1) a large and well-lighted class room for practical physiology and histology, fitted with motor and shafting, and with arrangements for lantern projection, (2) a laboratory for chemical physiology, (3) an apparatus room, (4) a dark room, (5) private research rooms, and (6) a centrifuge room The pathological laboratory —In this department opportunity is afforded for research in pathology and bacteriology The department is in touch with most of the hospitals in Belfast, and there is an ample supply of material for investigation by graduates in morbid histology, clinical pathology, and the bacteriology of infectious diseases A course in pathology or bacteriology is given to graduates and members of this class have an opportunity of seeing the methods employed in the various investigations carried out in the department for the Public Health Committee of the corporation in connexion with water supply, sewage disposal, meat- and milk supply, the diagnosis of cases of infectious diseases &c The certificate issued to members of the class in bacteriology qualifies for the D P H degree The pharmaceutical laboratory is fitted and equipped for the work of practically instructing students in the compounding and dispensing of medicines Clinical instruction is given at the Royal Hospital the medical staff of which is as follows —Physicians Professor Sir William Whitla, Dr J A. Lindsay, Dr W Calwell and Dr H L McKisack. Obstetrical Physician and Gynæcologist: Professor J W Byers Consulting Surgeons Dr H Murney and Mr J Fagan Surgeons Mr J W Browne Mr T K. Wheeler Professor T Sinclair and Mr A. B Mitchell. Assistant Surgeons Dr T S Kirk and Mr Robert Campbell. Assistant Physician Dr W B McQuitty Ophthalmic and Aural Surgeon Dr J Nelson. Pathologist Professor J L Smith. The Ulster Hospital for Diseases of Women and Children, the Maternity Hospital. the Ophthalmic Hospital the Ulster Eye, Ear and Throat Hospital, the Hospital for Sick Children and the District Lunatic Asylum are open to students A pamphlet containing full information can be had free on appplication to the Registrar Queen s College Belfast

---

[1] For Scholarships see page 641 et seq

QUEEN S COLLEGE SCHOOL OF MEDICINE, Cork.—The building is provided with a very large, well ventilated dissecting room supplied with electric light, with physiological, toxicological, pathological and pharmaceutical laboratories materia medica, anatomical and pathological museums, as well as a collection of surgical and obstetrical instruments and appliances. There are well appointed physical chemical and biological laboratories, and a large natural history museum in the adjoining building and part of the College ground is laid out as a botanical garden The plant houses are well filled with plants and are open to the students in the class of Botany

Fees —For Practical Anatomy and for Practical Chemistry £3 each course for Anatomy and Physiology £3 first course, and £2 for each subsequent course Other medical classes, £2 first course, and £1 each subsequent course.

Eight scholarships (value about £30 each) as well as several exhibitions and class prizes, are open to students in their first four years and the Blayney Scholarship value £35 and a S nior Exhibition to students in their fifth year

Students can attend the North and South Infirmaries, the Cork Union Hospital the Cork Fever Hospital the County and City of Cork Lying in Hospital the Cork Maternity the County and City of Cork Hospital for Di eases of Women and Children the Cork Eye Ear and Throat Hospital and the Cork District Lunatic Asylum.

Staff North Infirmary —Physicians Dr D D Donovan and Dr E. THE NAVAL, MILITARY, AND INDIAN MEDICAL SERVICES

DURING the year many changes for the better have been made in all the three great public services. The pay of the naval medical officers has been considerably increased and the position and pay of the officers of the Royal Army Medical Corps are now such that a good class of candidates should be attracted to its ranks. Whether the best class of men will enter knowing that a series of examinations is before them during their service remains to be seen but the authorities have made very important and beneficial changes in the entrance examination and in other important points and have worked out a scheme which may develop the Royal Army Medical Corps into a really fine service. So far the rulers of the Indian Medical Service have not seen their way to improving the position of its officers last year there was a great falling off in the number and quality of the candidates and unless the India Office rises to the occasion and considerably increases the pay of the officers we fear that the Indian Medical Service will no longer command the class of medical officer which has hitherto always preserved it as the premier medical service of the empire The India Office has made certain modifications in the entrance examination which are judicious and is, at all events for the present, continuing to send the probationers to the same course as the lieutenants of the Royal Army Medical Corps in London and subsequently to Netley for further instruction—a scheme which must be beneficial to the officers of both services as tending to promote that good fellowship and feeling which ought to prevail if the officers of the two services are to work as they should do in harmony in our Eastern possessions. A new warrant is looked for and is greatly desired by those who have the best interests of the Indian Medical Service at heart The India Office must recognise the fact that the price of skilled medical service has appreciated.

ROYAL NAVY MEDICAL SERVICE.

The next examination will probably take place in November next.

REGULATIONS FOR THE ENTRY OF CANDIDATES FOR COMMISSIONS IN THE MEDICAL DEPARTMENT OF THE ROYAL NAVY

Every candidate for admission into the Medical Department of the Royal Navy must be not under 21 nor over 28 years of age on the day of the commencement of the competitive examination He must produce an extract from the register of the date of his birth or in default, a declaration made before a magistrate from one of his parents or other near relative, stating the date of birth He must also produce a certificate of moral character up to date and a recommendation signed by a clergyman or magistrate to whom he has been for some years personally known or by the president or senior professor of the college at which he was educated.

He must be registered under the Medical Act in force as qualified to practise medicine and surgery in Great Britain and Ireland

He must declare (1) his age and date and place of birth; (2) that he is of pure European descent and the son either of natural born British subjects or of parents naturalised in the United Kingdom; (3) that he labours under no mental or constitutional disease or weakness nor any other imperfection or disability which may interfere with the most efficient discharge of the duties of a medical officer in any climate; (4) that he is ready to engage for general service at home or abroad as required (5) whether he holds or has held any commission or appointment in the public services; and (6) that he is registered under the Medical Act in force as duly qualified professionally and what diplomas &c., he holds *

He must be free from organic or other diseases and his physical fitness will be determined by a Board of Medical Officers who are to certify that his vision comes up to the required standard which will be ascertained by the use of Snellen's Test Types.

Candidates will be examined by the Examining Board in the following compulsory subjects and the highest number of marks attainable will be distributed as follows (a fee of £1 will have to be paid by each candidate to entitle him to take part in the competition) (a) medicine materia medica, therapeutics and general hygiene 1200 marks; (b) surgery and surgical anatomy 1200 marks. The examination in medicine and surgery will be in part practical and will include beyond papers the examination of patients the examination of pathological specimens, a knowledge of bacteriology the performance of operation on the dead body and the application of surgical apparatus The attention of candidates is especially drawn to the importance of the section of Operative Surgery as a competent knowledge in this subject is essential in order to qualify for a commission. No candidate shall be considered eligible who shall not have obtained at least *one-third* of the maximum marks in each of the above *compulsory subjects*

Candidates may be examined in the following voluntary subjects, for which the maximum number of marks obtainable will be—Natural Sciences chemistry (300); physiology (300); zoology (300); botany (300); and geology and physical geography (300) No candidate will be allowed to present himself for examination in more than two of these subjects French and German (300 each) 600 marks A number less than one-third of the marks obtainable in each of these *voluntary subjects* will not be allowed to count in favour of the candidate who has qualified in the *compulsory subjects* The knowledge of modern languages being considered of great importance all intending competitors are urged to qualify in French and German The examination in chemistry will include the general principles of inorganic and organic chemistry; the preparation and properties of the chief non metallic and metallic elements and their compounds; the preparation, properties and classification of the more important compounds such as marsh gas ethylene acetylene methyl and ethyl alcohols glycerin ether formic acetic, lactic and oxalic acids cyanogen and cyanides; carbohydrates; fats; proteids. The examination in physiology will comprise the minute structure and functions of the various tissues and organs of the body the physiology of the blood; the nature of food and the processes of its digestion; the mechanics of the circulation and of respiration; the physiology of nutrition secretion and excretion; animal heat the nature of sensation volition reflex action inhibition and influence of the nervous system on other organs and their functions The examination in zoology will include—the general principles of biology and a comparison of animals with plants; the distinctive characters of the larger groups of animals—the protozoa, coelenterata, vermes arthropoda, mollusca, echinodermata and vertebrata—as illustrated by common types the elements of embryology; animal parasites The examination in botany will comprise the general principles of the morphology and physiology of low forms of life—e.g., torula, bacteria spirogyra, moss fern; the general morphology of flowering plants; diagnosis of the important British natural orders; medicinal plants The examination in geology and physical geography will be limited to general principles such as—the relations of the earth to the rest of the solar system, nature of the earth's crust and the chief kinds of rocks, general configuration of land and water mountains plains islands rivers lakes glaciers and icebergs ocean currents tides wind storms, dew rain, climate volcanoes earthquakes distribution of animal and vegetable life

The appointments announced for competition will be filled from the list of qualified candidates arranged in order of merit but should it at any time be considered expedient to grant Commissions beyond those periodically competed for the Admiralty have power to admit annually (a) two candidates—proposed by the governing bodies of schools of medicine in the United Kingdom—who have satisfactorily filled the office of house surgeon in a large civil hospital for at least six months; and (b) not more than six candidates according to requirements [illegible] univer- [illegible] by the [illegible] granted [illegible] y and [illegible] a duly [illegible] candidates In cases of [illegible] qualifications may be deferred until after the arrival in England of a candidate who has been passed on the station but a Commission as Surgeon will not be granted until the certificate of the Registrar of the Medical Council has been produced at the Medical Department of the Navy Candidates from schools at home will be required to pass a physical examination in London which will be arranged for by the Medical Director General Colonial candidates will have to pass a physical and test examination before a board of Naval Medical Officers on the station. Successful candidates immediately after passing the examination in London will receive commissions as Surgeons [illegible] the Royal Navy and will undergo a course of practical instruction in Naval Hygiene, &c. at Haslar Hospital. Three prizes of the approximate value of £10 each will be awarded at the close of each [illegible] to the stu[illegible]

Surgeon [illegible] pocket ca[illegible] meters [illegible]

Promotion

An Inspector-General of Hospitals and Fleets will be selected from amongst Deputy Inspectors-General who have [illegible] in that rank three years full pay service and who have not at any time declined foreign service except for reasons which the Lords Commissioners of the Admiralty regard as good and sufficient.

A Deputy Inspector-General of Hospitals and Fleets will be selected for ability and merit from amongst Fleet Surgeons

---

† No returns.

* If any doubt should arise on the question the burden of the proof that he [illegible] will rest upon the candidate himself.

(a) Subject to the approval of the *Lords* Commissioners of the Admiralty rank as Fleet Surgeon will be granted to Staff Surgeons at the expiration of eight years from the date of promotion to Staff Surgeon, provided they are recommended by the Medical Director General and have not declined service except for reasons which in the opinion of the Lords Commissioners of the Admiralty are satisfactory (*b*) Special promotions from the rank of Staff Surgeon to that of Fleet Surgeon will be made at their Lordships' discretion in cases of distinguished service or conspicuous professional merit Such promotions will be exceptional and will not exceed the rate of one in two years the total number at any one time of Fleet Surgeons holding that rank by such special promotions will not exceed six

(*a*) Rank as Staff Surgeon will be granted subject to their Lordships approval to surgeons at the expiration of 12 years from the date of entry provided they are recommended by the Medical Director General and have passed such examination as may be required after completion of eight years from the date of entry in the rank of surgeon (*b*) Special promotions will be made at their Lordships discretion to the rank of Staff Surgeon in cases of distinguished service or conspicuous professional merit. Such promotions will be exceptional and not exceed the rate of one a year The total number at any one time of Staff Surgeons holding that rank by such special promotions will not exceed eight No officer will be so promoted unless he passes the examination prescribed for other surgeons but in such a case the requirement of eight years time in rank of surgeon will be dispensed with (*c*) When a surgeon s promotion to the rank of Staff Surgeon has been retarded by failure to pass the qualifying examination he will should he pass and be promoted be dealt with as follows He will be granted the seniority as Staff Surgeon he would have received had he passed in ordinary course He will reckon service for increase of full and half pay only from the date of appointment to full pay as Staff Surgeon If on half pay or if placed on half pay when promoted, he will receive the lowest rate of half pay of the new rank from the date of passing the qualifying examination Where delay in passing the qualifying examination may be due to unavoidable circumstances special consideration will be given (*d*) The seniority of surgeons on entry will be determined by the sum total of the marks they obtain at the London examination and those at the conclusion of the Haslar course and their names will then be placed in the official navy list Surgeons entered without competition will take seniority next after the last surgeon entered at the same time by competition (*e*) The examination for promotion to the rank of staff surgeon will be held by the Examining Board to which a naval medical officer will be attached to conduct the examination in naval hygiene. The subjects of examination will be in writing and will include medicine surgery pathology general hygiene naval hygiene Earlier promotion to the rank of staff surgeon may be granted to those surgeons who before entry have held the post of house surgeon to a civil hospital of not less than 100 beds for a period of not less than six months provided their conduct and professional abilities have been favourably reported on during the time they have served in the navy They may be granted from six months to one year s seniority according to the time they have held their civil appointments as house surgeon but in no case will more than one year s seniority be granted This only applies to officers who enter by competition

† Or on compulsory retirement at the age of 55

An officer retired with less than 20 years service on account of disability contracted in and attributable to the Service, will receive the half pay of his rank, or with the consent of their Lordships a gratuity on the scales given in paragraphs 16 and 18 (*b*) but such officer will not be entitled to receive any special compensation for the disability in addition to the gratuity as above (Paragraph 17).[1]

An officer retired with less that 20 years service on account of disability contracted in but not attributable to the Service, will receive—(*a*) if he has over eight years full-pay service either a gratuity on the scale given in Paragraph 16 or half-pay according as their Lordships think fit; (*b*) if he has less than eight years full pay service such gratuity as their Lordships think fit, not exceeding the rate of £125 for each year of full pay service (Paragraph 18). *In circumstances other than those specified in Paragraphs* 17 and 18, and other than misconduct, neglect of duty &c an officer retired with less than 20 years service will not be allowed half pay or retired pay but will receive a gratuity on the scale laid down in Paragraph 16 if he has eight years' full-pay service, and on that provided in Paragraph 18(*b*) should his full-pay service not amount to eight years The power vested in their Lordships of granting reduced rates of half pay and retired pay in cases of misconduct is extended to the award of gratuities on retirement, and the gratuity awarded will be reduced to such an amount as is thought fit. An officer retiring after 20 years full pay service will be eligible, if recommended by the Medical *Director-General* for distinguished or meritorious service to receive a step of honorary rank such step to be awarded at their Lordships discretion and not to confer any claim to increase of retired pay or of widow's pension All retired officers will be liable, till the age of 55 to serve in time of declared national emergency in a rank *not lower* than that held *on retirement.* Retired officers will receive special consideration as regards appointments on shore connected with the Admiralty now filled by civilians

Widows Pension

When an officer retires or withdraws *on a gratuity* his widow and children will have no claim to pension or compassionate allowance.

Miscellaneous

A special cabin will be appropriated to the Fleet or Staff Surgeon or the Surgeon in charge of the medical duties in each ship Special regulations have been made as regards the mess expenses of medical officers appointed to the several divisions of Royal Marines for limited periods Every medical officer will be required to undergo a post graduate course of three months duration at a Metropolitan Hospital once in every eight years (should the exigencies of the Service permit), and this as far as possible during his Surgeon's, Staff Surgeon's and *Fleet Surgeon's period of service.* While carrying out this course the medical officer will be borne on a ship's books for full pay and will be granted lodging and provision allowances and travelling expenses as for service under the Regulations to and from his home or port but he will be required to pay the necessary fees for each course. The medical officer will be required to produce separate certificates of efficient attendance in the following: (1) the medical and surgical practice of the hospital; (2) a course of operative surgery on the dead body; (3) a course of bacteriology; (4) a course of ophthalmic surgery particular attention being paid to the diagnosis of errors of refraction; and (5) a practical course of skiagraphy

Though the improvements which have been carried out in the Naval Medical Service are substantial we think that the department might still show greater regard for the medical officer The cabin accommodation for medical officers of the navy ought to be improved and senior officer at least, serving on men-of war might well have boats at their disposal to go on shore.

THE ARMY

Consequent upon the issue of the Royal Warrant published in Army Orders dated July 1st, 1898 the Army Medical Staff and the Medical Staff Corps were formed into the Royal Army Medical Corps. Medical officers also have been placed as regards sick leave of absence on full pay on the same footing as that laid down for regimental officers. By a Royal Warrant dated Nov 10th 1891 Art. 1208*b* of the Pay Warrant was revised by inserting the words an officer of *our Royal Army Medical Corps after the words combatant* officer" thus giving medical officers an equal title with combatant officers to reckon time on half pay toward retirement when the half pay has been due to ill health contracted in the performance of military duty Under the Royal Warrant of July 1895, time on half pay not exceeding a year may in similar circumstances also reckon towards promotion In the New Royal Warrant it was announced that the late Queen had been pleased to approve of the following rank for the officers of the Royal Army Medical Corps Colonel Lieutenant-Colonel Major Captain and Lieutenant The Warrant also states that the Medical Staff of the Army shall in future consist of Surgeon Generals (ranking as Major Generals) Officers of the *Royal Army Medical Corps* holding appointments in the Household Troops are to be borne as seconded officers on the establishment of the Royal Army Medical Corps

REGULATIONS FOR ADMISSION TO THE ROYAL ARMY MEDICAL CORPS (AS [illegible] BY ARMY ORDERS DATED MAY 1ST 190[illegible])

A candidate for a commission in the Royal Army Medical Corps must be 21 years and not over 28 years of age at the date of the commencement of the entrance examination He must possess a registrable qualification *to practise He must complete the subjoined form* of application and declaration and submit it to the Director-General, A M S

Application of a Candidate for a Commission in the Royal Army Medical Corps

1 Name in full .. ..

2. Address .. ..

3. Date of birth* .. ..

4 Registrable qualifications † ....

5. Academic and other distinctions .. ..

6 Name of the Dean or other responsible authority of the *school in which the candidate* completed his course as a medical student .. ..

7 Particulars of any commission or appointment held in the public services .. ..

8. Date of examination at which the candidate proposes to present himself .. ..

Declaration

(N.B —A mis-statement by the candidate will invalidate any subsequent appointment and cause forfeiture of all privileges for services rendered)

I hereby declare upon my honour that the above statements are true to the best of my knowledge and belief and that I am a British subject of unmixed European blood.

(Signed) ....

* A certificate of registration of birth or other satisfactory evidence of age such as a declaration made before a magistrate by one of his parents or guardians giving the date of his birth, to be furnished

† A reference to be given to the Medical Register or in the absence of such reference other satisfactory evidence to be furnished

The dean of the candidate's school will be requested by the Director General to render a confidential report as to his character conduct professional ability and fitness to hold a commission in the corps and to this report special importance will be attached. The Director General will decide if the candidate may be allowed to compete *for a commission* If approved he will then be examined as to his physical fitness by a board of medical officers. The following is the order of the examinations —

1 A candidate for a commission *in the Royal Army Medical Corps* must be in good mental and bodily health and free from any physical defect likely to interfere with the efficient performance of military duty

2. The examination will be conducted by a board of medical officers

3 The attention of the board will be directed to the following points (*a*) That the correlation of age height weight and chest girth is equal or superior to that which is given in the following table —

Physical Equivalents

Age	Height without shoes	Chest	
		Girth when expanded.	Range of expansion
21 and upwards.	Inches 62½ and under 65 65 [illegible] 68 68 [illegible] 70 70 [illegible] 72 72 and upward	35 inches 35½ 36 36½ ,, 37 ,,	2 inches, 2 ,, 2 ,, 2½ 2½

(*b*) Measurement of height The candidate will be placed against the standard with his feet together and the weight thrown on the heels and not on the toes or outside of the feet He will stand erect without rigidity and with the heels calves buttocks and shoulders touching the standard; the chin will be depressed to bring the vertex of the head level under the horizontal bar and the height will be noted in parts of an inch to eighths.

(*c*) Measurement of chest The candidate will be made to stand erect with his feet together and to raise his hands above his head The tape will be carefully adjusted round the chest with its [illegible] upper edge touching the inferior angles of the shoulder blades and its upper edge touching the upper part of the nipples The arms will then be lowered to hang loosely by the side and care will be taken that the shoulders are not thrown upwards or backwards so as to displace the tape The candidate will then be directed to empty his chest [illegible] tape [illegible] This [illegible] [illegible] The tape [illegible] the lips [illegible] [illegible] [illegible] to its utmost capacity [illegible] noted The girth with the chest [illegible] expansion between the minimum and maximum [illegible]

(*f*) Weight [illegible] of the Board [illegible]

The regulations [illegible] as follows —

1 If a candidate can read D = 6 at 6 metres [illegible]

---

[1] If the health of a surgeon breaks down before he completes [illegible] years service even if the disability be contracted in the Service or be due to climate [illegible] he will be placed on the retired list receiving only a gratuity This point should be well noted [illegible]

D =0 6, at any distance selected by himself, with each eye without glasses, he will be considered *fit*

2. If a candidate can only read D =24 at 6 metres (20 English feet) with each eye without glasses his visual deficiency being due to faulty refraction which can be corrected by glasses which enable him to read D =6 at 6 metres (20 English feet) with one eye and D =12, at the same distance with the other eye and can also read D =0 8 with each eye without glasses at any distance selected by himself he will be considered *fit*.

3 If a candidate cannot read D =24 at 6 metres (20 English feet) with each eye without glasses notwithstanding he can read D =0 6 he will be considered *unfit* Normal vision of one eye may be sufficient to allow a higher defect in the other to the extent of one-sixth if the defect is simple error in refraction remedied by glasses The candidate must be able to read the tests without hesitation in ordinary daylight (N B —Snellen s test types will be used for determining the acuteness of vision) Squint inability to distinguish the principal colours, or any morbid conditions subject to the risk of aggravation or recurrence in either eye will cause the rejection of a candidate

The following additional points will then be observed (*b*) That his hearing is good (*c*) That his speech is without impediment (*d*) That his teeth are in good order Loss or decay of the teeth will be considered a disqualification Decayed teeth if well filled will be considered as sound (*e*) That his chest is well formed and that his heart and lungs are sound (*f*) That he is not ruptured (*g*) That he does not suffer from hydrocele varicocele varicose veins in a severe degree or other disease likely to cause inefficiency A slight defect if successfully cured by operation is not a disqualification (*h*) That his limbs are well formed and developed (*i*) That there is free and perfect motion of all the joints (*j*) That his feet and toes are well formed (*k*) That he does not suffer from any inveterate skin disease (*l*) That he has no congenital malformation or defect (*m*) That he does not bear traces of previous acute or chronic disease pointing to an impaired constitution In any doubtful case the Board should further state: (*n*) Whether he is in their opinion of pure European descent If a candidate be pronounced physically fit for service at home and abroad he will be eligible to present himself at the entrance examination which will be held twice in the year

The Secretary of State reserves the right of rejecting any candidate who may show a deficiency in his general education

An entrance fee of £1 is required from each candidate admitted to the examination and is payable at the conclusion of his physical examination if pronounced fit.

A candidate successful at the entrance examination will be appointed a Lieutenant on probation and will be required to pass through such courses of instruction as the Secretary of State shall decide and after passing the examinations in the subjects taught and satisfying the Director General that he possesses the necessary skill knowledge and character for permanent appointment to the Royal Army Medical Corps his commission as Lieutenant will be confirmed The commission shall bear the date of the officer s appointment as Lieutenant on probation

Before the commission of a Lieutenant on probation is confirmed he must be registered under the Medical Acts in force in the United Kingdom at the time of his appointment

The precedence of Lieutenants among each other shall be in order of merit as determined by the combined results of the entrance examination and the examinations undergone while on probation

Lieutenants when appointed on probation will receive instructions as to the provision of uniform

EXAMINATIONS

Subjects for the Entrance Examination

Candidates will be examined by the examining board in medicine and surgery The examination will be of a clinical and practical character, partly written and partly oral marks being allotted under the following scheme:—

	Maximum marks
Medicine (written)	
A. Examination and report upon a medical case in the wards of a hospital	125
B Commentary upon a case in medicine	125
(Three hours allowed for A and B together)	
Medicine (oral)	
A Clinical cases clinical pathology	75
B Morbid Anatomy and Morbid Histology	75
(One quarter of an hour allowed for each table)	
Surgery (writen)	
A. Examination and report upon a surgical case in the wards of a hospital	125
B Commentary upon a case in surgery	125
(Three hours allowed for A and B together)	
Surgery (oral)	
A Clinical cases including diseases of the eye surgical instruments and appliances	75
(One quarter of an hour allowed for this table)	
B Operative surgery and surgical anatomy	75
Total marks	800

The following headings are published as a guide to candidates in drawing up their reports on cases —(*a*) A brief history of the case as given by the patient, including such points only (if any) in the family or personal history as have a distinct bearing upon the present illness or incapacity (*b*) A detailed account of the subjective symptoms and physical signs elicited by the candidate s personal examination of the patient noting the absence of any which might be expected to be present in a similar case (c) Where there is any reasonable doubt in the mind of the candidate as to an exact diagnosis he is to give the alternatives with his reasons for making the selection (*d*) A commentary upon the case as a whole, pointing out the symptoms which may be considered typical and those which appear to be unusual or only accidental complications (*e*) Suggestions as to treatment both immediate and possibly necessary at a later date (*f*) A forecast of the progress and probable termination of the case

Similarly the commentary on the report of a case submitted to the candidate should discuss: (*a*) The family and personal history and other conditions preceding the development of the condition described (*b*) The relative significance of the physical signs, symptoms other indications of disease noted and the general clinical aspects of the case (*c*) The diagnosis, with reasons for selection of the most probable, when a positive diagnosis cannot be attained (*d*) The treatment dietetic, medicinal, operative, &c including a criticism of the plan adopted, and alternative schemes of treatment in case of disagreement (*e*) The morbid appearances and an account of the post-mortem examination (if any)

The examination will be held in London and will occupy about four days

The appointments announced for the competition will be filled up from the list of qualified candidates arranged in the order of merit, as determined by the total number of marks each has obtained Having gained a place in this entrance examination the successful candidates will undergo two months' instruction in hygiene and bacteriology, after which they will be examined in these subjects. The maximum number of marks obtainable at this examination will be 100 It has been determined that this course shall be delivered in London and not as heretofore at Netley A military medical staff college is to be built in London and until the new buildings are completed the instruction will be given in the laboratories of the Conjoint Board on the Thames Embankment. At the present time the professors are Dr A E Wright in the department of bacteriology, and Major H. R Firth in that of hygiene, Major W B Leishman and Major W H Horrocks, both of the Royal Army Medical Corps, being the respective assistant professors The first course of instruction in London commences on Sept. 1st next The course of hygiene has hitherto comprised the examinations of water and air, the general principles of diet with the quality and adulterations of food and beverages, the sanitary requirements of barracks, hospitals, and camps, the consideration of the clothing, duties, and exercises of the soldier, and the circumstances affecting his health, with the best means of preventing disease and instruction in the mode of preparing the various statistical and other returns required of the medical officer The pathological course has up to the present time included bacteriology and demonstrations in physiological chemistry On completion of the above course lieutenants on probation will be ordered to proceed to the depôt of the Royal Army Medical Corps at Aldershot for a three months' course of instruction in the technical duties of the corps, and at the end of the course will be examined in the subjects taught The maximum number of marks obtainable at this examination will be 100 A lieutenant on probation who fails to qualify in either of these examinations will be allowed a second trial, and, should he qualify, will be placed at the bottom of the list. Should he again fail in either examination his commission will not be confirmed

EXAMINATIONS FOR PROMOTION IN THE ROYAL ARMY MEDICAL CORPS

These examinations are intended to test the progress and proficiency of officers in those branches of knowledge which are essential to their continued efficiency

Lieutenant before Promotion to Captain —(For Lieutenants appointed after March 31st 1901) This examination may be taken at any time after completing 18 months service and will be held in the military district in which the officer is serving The subjects of this examination which are detailed in the King's Regulations are as follows: (1) regimental duties (2) drill (3) military law (4) duties and accounts connected with military hospitals and their supplies and (5) other duties of executive medical officers

Captains before Promotion to Major —(For Captains promoted to that rank after July 27th 1895) Captains will be examined under the rules laid down in Paragraph 24 and will be eligible for acceleration in their promotion to the rank of Major under Article 352 of the Royal Warrant subject to the following restrictions—(*a*) The acceleration which can be gained by a Captain promoted to that rank in January, 1896 will be limited to six months and an officer gaining this acceleration will take precedence after the last Captain promoted Major on completion of 12 years service (*b*) The acceleration which can be gained by a Captain promoted to that rank in July 1896, will similarly be limited to 12 months and an officer gaining this acceleration will take precedence next after the last Captain promoted to that rank in January 1896 who may have gained six months service. (*c*) A Captain promoted to that rank in January 1897 can gain the full acceleration but will take precedence after any captain promoted to that rank in July 1896 who may have gained 12 months acceleration (*d*) Officers gaining acceleration under (*a*) will take precedence *inter se* in order as they have obtained a special certificate or passed in the first, second or third class and a similar course will be followed under (*b*) and (*c*) (*e*) In all other cases an officer who gains accelerated promotion will be placed for precedence after the last officer (whether subject to acceleration or not) promoted approximately 3, 6 12, or 18 months before him

This examination which may be taken at any time after completing five years service will be held in London on the termination of a period of special study The examination will consist of written papers, essays oral and practical examinations in the following subjects which are detailed in the King's Regulations: (1) medicine (2) surgery (3) hygiene (4) bacteriology and tropical disease; and (5) one special subject from the subjoined list to which additions may from time to time be made: (a) bacteriology including the preparation of antitoxins; (b) dental surgery; (c) dermatology; (d) laryngology; (e) midwifery and gynæcology; (f) operative surgery advanced; (g) ophthalmology; (h) otology; (i) pediatrics; (k) psychological medicine; (l) skiagraphy; and (m) specific fevers Captains serving in that rank before July 27th 1895, will be promoted under the old regulations contained in Appendix I Regulations for Army Medical Services and will not be eligible for acceleration

Majors before Promotion to Lieutenant-Colonel (for Majors promoted to the rank after March 31st 1895) —This examination, which may be taken at any time after three years in the rank of Major will be held in the military district in which the officer is serving at times which will be duly notified. The subjects of this examination which are detailed in the King's Regulations, are as follows: 1 Military law 2. Army medical organisation 3. Sanitation of towns camps transports, &c 4. Epidemiology and the management of epidemics 5. One special subject from the subjoined list to which additions may from time to time be made: (a) medical history of important campaigns; (b) a general knowledge of the Army Medical Services of other Powers; and (c) the laws and customs of war in relation to the sick wounded

PAY

The following shall be the rates of pay additional pay and charge pay of the Army Medical Staff and Royal Army Medical Corps:—

Army Medical Service	Inclusive of all allowances except field and travelling allowances (yearly)
At Headquarters	£
Director-General	2000

Assistant Director General	850
Deputy Assistant Director-General	750
	Exclusive of allowances (daily)
At Other Stations	£ s d
Surgeon General	3 0 0
Colonel	2 0 0
Lieutenant-Colonel	1 10 0
Lieutenant-Colonel specially selected for increased pay after at least eight years service abroad	1 15 0
Major	1 3 6
After three years as such	1 6 0
Captain	0 15 6
After seven years total full-pay service	0 17 0
After ten years total full pay service	1 1 0
Lieutenant on probation and Lieutenant	0 14 0
Adjutant of the Royal Army Medical Corps (Volunteers)	The pay of his rank

A Captain of the Royal Army Medical Corps holding the brevet rank of Major shall receive pay at 2s a day in addition to the rates laid down.

Additional Pay

An officer not serving on the Headquarters Staff appointed a member of the Advisory Board £150 a year An officer serving as secretary of the Advisory Board and Nursing Board £100 a year An officer under the rank of Lieutenant Colonel holding an appointment as specialist, 2s 6d daily

Charge Pay

(a) An officer in charge of a general or other hospital or of a division of a general hospital—

	Daily s d
If in charge of at least 50 beds	[illegible] 6
" 100	5 0
" 200	7 6
" 300	10 0
(b) Officer in command of the Depôt Royal Army Medical Corps	5 0
(c) The Senior officer of the Army Medical Service with an army in the field— A rate to be fixed by the Secretary of State according to the magnitude of the charge.	
(d) In a command abroad— The senior medical officer if the number of soldiers is 1500 or upwards	5 0

Extra-duty Pay

An officer of the Royal Army Medical Corps appointed to act as adjutant or quartermaster of the Royal Army Medical Corps (Militia) during preliminary drill or training shall receive extra-duty pay at the following rates:—

	Daily s d
Acting Adjutant	2 6
Acting Quartermaster	2 0

Reserve of Officers

On completion of three years service an officer of the Royal Army Medical Corps may be permitted by the Secretary of State to [illegible] an Army Reserve Officer for a period of seven years and [illegible] so serving he shall receive pay at the rate of £25 a year With the sanction of the Secretary of State such officer may be allowed to return to the active list and if the [illegible] in the reserve of [illegible] amounted to at least one year [illegible] he shall be allowed to reckon one third [illegible] towards promotion gratuity and pension

[illegible] Officers

A Lieutenant on probation who at the time of passing the examination [illegible] admission to the Royal Army Medical Corps [illegible] to hold a resident appointment in a recognised civil hospital may be seconded for a period not exceeding one year during which he holds the appointment While seconded he shall not receive pay from army funds but his service shall reckon towards promotion increase of pay gratuity and pension

PROMOTION

Every promotion of a medical or departmental officer shall be given upon the recommendation of the Commander in Chief with the approval of the Secretary of State Promotion by selection shall be given on the ground of ability and merit due consideration being given, however to length of efficient service

An officer shall be eligible for promotion to the rank of Captain on the completion of three and a half years service and to the rank of Major on the completion of 12 years' service provided that in each case he has previously qualified in such manner as may be prescribed by the Secretary of State

Promotion to the rank of Lieutenant-Colonel shall be made by selection from officers who have completed at least 20 years service and have qualified in such manner as may be prescribed by the Secretary of State

If an officer has passed with distinction the examination qualifying for promotion to the rank of Major the period of service required to render him eligible for the rank of Major or Lieutenant-Colonel may be reduced as follows:—

	Months
If he obtained a "special certificate	18
passed in the 1st Class	12
2nd "	6
3rd	3

Promotion to the rank of Colonel shall be made by selection from Lieutenant-Colonels who have been specially selected for increased pay and from Lieutenant-Colonels or Surgeon Lieutenant-Colonels of the Household Troops specially recommended to the Secretary of State for distinguished service in the field Promotion to the rank of Surgeon General shall be made by selection from Colonels. A Colonel may also be promoted to the rank of *Surgeon-General for distinguished service* in the field In cases of distinguished service in the field a departmental officer may [illegible] the Treasury be pr[illegible] and shall if promo[illegible] remain supernumerary [illegible] rank or class until the occurrence of the vacancy to which in the ordinary course he would have been promoted. An officer of the Royal Army Medical Corps is eligible for promotion to brevet rank. A captain after at least 6 years service a Major or Lieutenant-Colonel, may be promoted to the next higher rank by brevet for distinguished service in the field or for distinguished service of an exceptional nature other than in the field. If the officer dies before the date on which the notification of his promotion for distinguished service in the field appears in the *London Gazette* the promotion shall bear the date which it would have borne had the officer not died Distinction in original investigation or research may, in the case of officers of the Royal Army Medical Corps be regarded as "distinguished service of an exceptional nature other than in the field." An officer who does not qualify for promotion to the rank of Captain or Major within the periods specified shall be placed on the supernumerary list until he qualifies or is retired from the service Service on the supernumerary list shall not reckon towards promotion increase of pay gratuity or pension

RANK

The Director-General of the Army Medical Service shall hold the substantive rank of Surgeon-General and shall rank in relation to combatant officers as a Lieutenant General. All other Surgeon Generals shall rank as Major-Generals in relation to combatant officers.

RETIREMENT

An officer of the Army Medical Service will be permitted to retire in cases in which such retirement may be deemed expedient by the Secretary of State.

Scale of Retired Pay

	Yearly £
Director-General after 3 years service in the appointment (with 30 years service)	1125
Under 3 years service as Director General and after not less than 30 years service	[illegible]
	Daily £ s d
Surgeon-General	[illegible] 0 0
Colonel R.A.M.C. and Household Troops	1 15 0
Lieutenant-Colonel R.A.M.C. and Surgeon-Lieutenant-Colonel Household Troops—	
After 20 years service	1 [illegible]
25	1 2 [illegible]
30	1 5 0
Lieutenant-Colonel after having been in receipt of the increased pay [illegible] for 3 years or a Brigade Surgeon Lieutenant Colonel of the Household Troops—	
Under 30 years service	1 [illegible]
After 30	1 10 0
Major or Surgeon Major of the Household Troops—	
After 20 years service	1 0 0
15 years service if his service reckoning for promotion is insufficient to qualify him for promotion to the rank of Lieutenant Colonel under Article [illegible]	[illegible] Gratuity
Major or Captain—	
After 5 years service [illegible] rank of captain	[illegible]
3 [illegible]	[illegible]
6	[illegible]
Surgeon Lieutenant Colonel or Surgeon Major of the Household Troops—	
After 15 years service	[illegible]
[illegible]	[illegible]

[illegible] Medical Service [illegible] three years in the rank [illegible] the gratuity [illegible]

Retirement on Account of Age or Limitation of Period of Service.

The Director General of the Army Medical Service shall retire on completion of the term of his appointment and the retirement of other officers of the Army Medical Service (except Quartermasters) shall be compulsory at the following ages: Surgeon General, 60 Colonel 57 and other officers 55 A Major shall retire on completion of 25 years service or if he fails to qualify for promotion on completion of 20 years service A Captain or Lieutenant shall retire on completing six months' service on the Supernumerary list It shall be competent to the Secretary of State to place a medical officer on the retired list after 30 years service

Retirement on Account of Medical Unfitness

An officer of the Army Medical Service or a medical officer of the Royal Malta Artillery placed on the half pay list on account of medical unfitness shall if not previously retired be retired from the Army at the expiration of five years from the date on which he was placed on the half pay list or if reported by the regulated medical authority to be permanently unfit for duty on the officer s application, at such earlier date as may be decided by the Secretary of State.

An officer whether on full pay or half pay placed in detention as a person of unsound mind shall be retired from the Army with the retired pay to which he would be entitled if reported by the regulated medical authority to be permanently unfit for duty If his disability was not caused by military service and he is not entitled to permanent retired pay by length of service he shall receive temporary retired pay equivalent to the half pay and temporary retired pay if any which he would have received if his disability had been other than insanity

Rates of Officers not qualified for Retired Pay on Voluntary Retirement

If the unfitness was caused by military service retired pay equal to the half pay of his rank If not so caused, provided the officer has at least 12 years service retired pay equal to the half pay of his rank for such period only not exceeding five years from the date of the officer s retirement from the Army after five years on half pay under Article 306 as the Secretary of State shall determine according to the merits of the case

KING S HONORARY PHYSICIANS AND HONORARY SURGEONS

Six of the most meritorious officers of the Army Medical Service shall be named Honorary Physicians and six Honorary Surgeons On appointment as Honorary Physician or Honorary Surgeon an officer under the rank of Colonel in the Royal Army Medical Corps may be promoted to the brevet rank of Colonel A Lieutenant-Colonel appointed Honorary Physician or Honorary Surgeon shall receive pay at the rate laid down for a Colonel of the Royal Army Medical Corps when qualified for promotion to that rank

MEDICAL OFFICERS OF THE REGIMENTS OF HOUSEHOLD TROOPS

Appointment

A Major or Lieutenant Colonel of the Royal Army Medical Corps may on the nomination of the titular colonel of the regiment be transferred from his corps into the rank of Surgeon Major or Surgeon Lieutenant Colonel respectively in one of the regiments of Household Troops

Pay

	£	s	d
Brigade Surgeon Lieutenant Colonel	1	15	0
Surgeon Lieutenant Colonel	1	10	0
Surgeon Major	1	3	6
After three years service as such	1	6	0

Promotion

A Surgeon Major shall be eligible for promotion to the rank of Surgeon Lieutenant Colonel on completing 20 years service, provided that he has previously qualified in such manner as may be prescribed by the Secretary of State Promotion to the rank of Brigade-Surgeon Lieutenant Colonel shall be made by seniority on the medical establishment of the brigade

A Surgeon Major may be promoted to the rank of Surgeon Lieutenant-Colonel for distinguished service in the field

EXCHANGES AND TRANSFERS

An officer of the Royal Army Medical Corps shall be permitted to exchange with another officer of such corps or with a medical officer of the Household Troops under such conditions and regulations as may from time to time be made

A medical officer of the Household Troops may be permitted to exchange with an officer of the Royal Army Medical Corps provided that an officer exchanging into the Royal Army Medical Corps has fulfilled any conditions as to service abroad required of officers of such corps

Exchanges between officers of the Royal Army Medical Corps under the rank of Major and medical officers of Indian Military Forces and transfers of such officers from either of the above services to the other shall only be permitted subject to the approval of the Secretary of State for India in Council and on the following conditions (1) That the officers have less than seven years service (2) that the senior officer exchanging takes the place of the junior on the list and shall not be promoted until the officer next above him has been so promoted (3) that the junior officer exchanging is placed for seniority next below all medical officers whose commissions have the same date as his own and (4) that the officer transferred is placed for seniority below all medical officers holding the same rank at the time of his transfer and shall not be promoted until the officer next above him has been promoted

An Officer of the Royal Army Medical Corps who has exchanged or been transferred from the Indian Military Forces shall reckon subject to the conditions of that article his previous service with the said forces towards promotion increase of pay gratuity and pension

LEAVE OF ABSENCE.

Full pay during ordinary leave of absence for the period admissible in the case of a staff officer may be granted to a medical officer provided that no additional expense is incurred thereby

When the periods of leave referred to in Article 457 have been exhausted or exceeded in consequence of sickness no further pay during ordinary leave shall remain due.

SICK LEAVE.

An officer of the Army Medical Staff or Royal Army Medical Corps may be allowed full pay during sick leave of absence on the same conditions as those laid down for regimental officers

SERVICE ON THE WEST COAST OF AFRICA

An officer volunteering for or ordered to, the West Coast of Africa shall receive double pay while actually serving on the coast, and for any time spent at Madeira or the Canary Islands on sick leave or on ordinary leave not exceeding 61 days in a year

For each year s service on the coast a medical officer shall be entitled to full pay during a year s leave at home and for every additional period beyond a year he shall have an equivalent extension of full pay during leave

Each year or portion of a year served on the West Coast of Africa by an officer of the Royal Army Medical Corps shall reckon double towards voluntary retirement or retired pay provided that he has served 12 months on the coast In ordinary cases the 12 months may be made up of two separate periods of not less than six months each and if an officer leaves the coast on account of sickness he may reckon any period of service on the coast however short in order to make up the 12 months coast service which is required to entitle him to count his service double Except when the officer has been invalided any broken period if amounting to less than six months of service on the coast, and leave on full pay, shall not reckon double under this article

WIDOWS PENSIONS

Widows pensions and compassionate allowances for children and other relatives of deceased officers are given under certain conditions specified in the Royal Warrant for Pay and Promotion There is also an Army Medical Officers Widows Annuity Fund on mutual assurance principles

INDIAN MEDICAL SERVICE.

The grades of officers in the Indian Medical Service are the same as those of the Army Medical Service and Royal Army Medical Corps

REGULATIONS FOR THE EXAMINATION OF CANDIDATES FOR ADMISSION TO THE INDIAN MEDICAL SERVICE

Candidates must be natural born subjects of His Majesty, between 21 and 28 years of age at the date of the examination of sound bodily health and in the opinion of the Secretary of State for India in Council in all respects suitable to hold commissions in the Indian Medical Service. They may be married or unmarried They must possess a diploma or diplomas entitling them under the Medical Acts to practise both medicine and surgery in Great Britain and Ireland

They must subscribe and send in to the Military Secretary India Office Westminster *so as to reach that address by the date fixed in the advertisement of the examination* a declaration according to the annexed form

Declaration and Schedule of Qualifications to be Filled up by Candidates

* I ..

Years of Age in last *vide accompanying Certificate* a Candidate for employment in His Majesty s Indian Medical Service do hereby attest my readiness to engage for that service and to proceed on duty immediately on being gazetted

I declare that I labour under no Mental or Constitutional Disease nor *any imperfection* or disability that can interfere with the most efficient discharge of the Duties of a Medical Officer

† I have the Degree of A.M or A B from the

I have the Degree of M D or M B from the ..

I have a Licence to Practise Medicine from the ..

I have a Diploma in Surgery from the

‡ I have a Licence to Practise Surgery from the

..

(Signature at full length) .. ..

(Date)

(Place of residence) ..

Candidates who desire to undergo the voluntary examination are to sign the following declaration:—

It is my intention to undergo the voluntary examination in §

* Christian and surname at full length

† The dates of graduations and the universities or colleges are to be stated

‡ The candidate should here state whether he has served in the Medical Department of the Army or Navy or in the subordinate Medical Department in India

§ State whether Botany or Zoology will be taken up

This declaration must be accompanied by the following documents:— *a* *Proof of age* either by Registrar General s certificate, or where such certificate is unattainable by the candidate s own statutory declaration form of which can be obtained at the India Office supported, if required by the Secretary of State by such evidence as he may consider satisfactory A certificate of baptism which does not afford proof of age will be useless *b* A recommendation from some person of standing in society—not a member of his own family—to the effect that he is of regular and steady habits and likely in every respect to prove creditable to the service if admitted and a certificate of moral character from a magistrate or a minister of the religious denomination to which the candidate belongs *c* *A certificate of registration* under the Medical Acts of the degrees diplomas, and licences possessed by the candidate. *d* A certificate of having attended a course of instruction for not less than three *months* at an ophthalmic hospital or the ophthalmic department of a general hospital which course shall include instruction in the errors of refraction.

The physical fitness of each candidate will be determined by a Board of Medical Officers who are required to certify that his vision is sufficiently good to enable him to pass the tests laid down by the regulations Every *candidate must also be free* from all other organic disease and from constitutional weakness or other disability likely to unfit him for military service in India. The standard of eyesight is the same as for the Royal Army Medical Corps and the physical examination is in all respects the same (see under Royal Army Medical Corps). Candidates who pass the physical examination will be required to pay a fee of £1 before being permitted to compete. No candidate will be permitted to compete more than three times.

On producing the foregoing qualifications the candidate will be examined by the Examining Board in the following subjects and the highest number of marks attainable will be distributed as follows:—

	Marks.
1. Medicine, including therapeutics	1200
2. Surgery including diseases of the eye	1200
3. Surgical anatomy and physiology	600
4. Pathology and bacteriology	600
5. Midwifery and diseases of women and children	600
6. Chemistry and pharmacy with either botany or zoology	600

N.B.—The examination in medicine and surgery will be in part practical and will include operations on the dead body the application of surgical apparatus and the examination of medical and surgical patients at the bedside. The examination in chemistry will be limited to the elements of the science and to its application to medicine pharmacy, and practical hygiene. No candidate shall be considered eligible who shall not have obtained at least *one third* of the marks obtainable in each of the above subjects and *one half* of the aggregate marks for all the subjects.

After passing this examination the successful candidates will be required to attend one entire course of practical instruction at the Army Medical School and elsewhere, as may be decided in (1) hygiene, (2) clinical and military medicine, (3) clinical and military surgery and (4) pathology of diseases and injuries incidental to military service. This course will be of not less than four months duration.*

During this period of instruction each candidate will receive an allowance of 8s per diem with quarters with the usual fuel and light allowances of a subaltern to cover all costs of maintenance, and he will be required to provide himself with uniform (viz., the regulation undress uniform and mess dress of a Lieutenant of the Indian Medical Service, as described in Indian Army Regulations Vol. VII but without the sword).

Candidates will be required to conform to such rules of discipline as may from time to time be laid down.

At the conclusion of the course candidates will be required to pass an examination on the subjects taught during the course of instruction.

Officers appointed to the Indian Medical Service will be placed on one list, their position on it being determined by the combined results of the preliminary and final examinations and so far as the requirements of the service will permit, they will have the choice of commands in India (i.e. Bengal Punjab Madras or Bombay) *according to their* position on that list. Though ordinarily employed within the limits of the command to which they may have been posted they will be liable to employment in any part of India according to the exigencies of the service. Examinations for admission to the service usually take place twice in the year—i.e. about February and August.

At Netley the probationers for the Indian Medical Service are required to attend the Royal Army Medical Corps mess *and to conform to the rules and regulations thereof.* The staff of the school at Netley consists of two professors. The Professorship of Military Medicine is held by Colonel K. Macleod, M.D. I.M.S. Colonel W. F. Stevenson M.B. C.B. is Professor of Military Surgery. The lectures on Military Surgery include gunshot and other wounds transport of sick and wounded, duties of army medical officers in the field on board troopships and transports, recruiting and other duties incident to military service. Those on Military Medicine treat of tropical and other diseases to which soldiers are exposed in the course of their service, the mortality and invaliding by disease, in peace and war at home and abroad the management of lunatics under the conditions of military service, &c. The course of six lectures on Lunacy and Military Asylum work is delivered at the Netley Lunatic Asylum by Lieutenant-Colonel Chester M.B. The probationers are detailed for duty in the wards of the hospital under the Professors of Medicine and Surgery. There they are taught practically the details of the management of patients in a military hospital, the registration of their diseases the duties of invaliding the modes of filling up the regulation statistical returns, and other service documents. The probationers are provided with quarters and are extra members of the mess at Netley. They are required to provide themselves with the regulation undress and mess uniform of a Lieutenant but without the sword sword belt, dress trousers forage cap, patrol jacket, and badge of rank. After having passed through the course of instruction they are required to pass a qualifying examination in the subjects taught in the school and their position on the list of those recommended for commissions is determined by the combined results of the competitive and final examinations. At the close of each session nine prizes have hitherto been awarded the Herbert Prize of £20 to the surgeon-on probation who has obtained the highest number of marks at the Netley examination the Parkes Memorial Bronze Medal to the one who gains the highest number of marks in the examination in Hygiene, the de Chaumont prize of books to the one who takes second place in Hygiene the Martin Memorial Gold Medal for the highest number of marks in the examination of Military Medicine the Montefiore Medal and £21 awarded for Military Surgery the Montefiore Second Prize, a cheque to the surgeon-on probation who obtains the second highest number of marks in this branch the Maclean prize of books for Clinical Medicine and Surgery and for Ward Work a prize of books for the highest number of marks gained in Pathology and the Marshall Webb prize of £5 and a bronze medal for Hospital Administration. No ruling has as yet been promulgated with regard to the distribution of these prizes in the future. Hitherto they have been equally open to the officers of either service, but as the Lieutenants of the Royal Army Medical Corps are only to be instructed in Hygiene and Bacteriology it would appear that the prize in these subjects will be alone open to the dual competition and that the other prizes will be open to the probationers of the Indian Service only.

At the close of the Netley Session those surgeons-on probation who have obtained one-third of the possible total of marks in each subject and have satisfied the authorities that they possess the necessary skill, knowledge, and character for permanent appointment are recommended for commissions as Lieutenants in the Indian Medical Service.

Officers on appointment are when possible, provided with passage to India by troopship, when troopship accommodation is not available passage at the public expense is provided by steamer or a passage allowance granted if preferred. A charge for messing during the voyage is made at the rate of 2s a day. This payment does not include the *cost of* liquors which are charged for as extras. Any officer who may neglect or refuse to proceed to India under the orders of the Secretary of State for India within two months from the date of leaving Netley will be considered as having forfeited his appointment unless special circumstances shall justify a departure from this regulation. A Lieutenant's commission is dated from the day he passes out of the Army Medical School. Lieutenants are promoted to the rank of Captain on completing three years full pay service Captains to the rank of Major after 12 years full pay service and Majors to the rank of Lieutenant-Colonel after 20 years full pay service. No examination to qualify for promotion is required. All promotions to higher grades are to be given by selection for ability and merit. In case of distinguished service in the field a medical officer may be at once promoted from any rank to the one next above it, remaining supernumerary in the higher rank until he would have been *promoted in ordinary* course or until selected for further promotion for which he is eligible. The ages for compulsory retirement are the same as those for the Royal Army Medical Corps. Officers of the Indian Medical Service below the rank of Colonel may be granted 1. Privilege leave under such regulations as may from time to time be in force. 2. Leave out of India for no longer period than one year capable of extension to two years absence from duty on the following pay:—After arrival in India, *on first* appointment £200 a year after the commencement of the fifth year's service for pension £250 a year after the commencement of the tenth year's service for pension £300 a year after the commencement of the fifteenth year's service for pension £400 a year after the commencement of the twentieth year's service for pension £450 a year and after the commencement of the twenty fifth year's service for pension, £500 a year. 3. Leave in India, but for the period of one year only on *full military pay* and half the staff salary of appointment. No extension of leave involving absence from duty for more than two years whether taken in or out of India, can be granted except on specially urgent grounds and without pay. An officer unable on account of the state of his health to return to duty within the maximum period of two years absence unless he is specially granted an extension [illegible] without pay is placed on temporary half pay or the retired list as the circumstances of the case may require. An officer is also liable to be placed on half pay or the retired list should his health require an undue amount of leave whether in or out of India. Leave may be granted at any time but solely at the discretion of the Commander-in-Chief or of the Local Governments in India in the case of officers not under the direct orders of a Commander in Chief. Officers of the Administrative grades may be granted one period of leave not exceeding eight months during their tenure of appointment. An officer on leave is required to join at once on being recalled to duty unless certified by a medical board as unfit to do so

---

* For the present it has been arranged that two months of the course will be spent in London where the probationers will be instructed with the Lieutenants on probation for the Royal Army Medical Corps in Hygiene and Bacteriology. The probationers for the Indian Service will subsequently proceed to Netley for a two months course in military surgery tropical medicine and asylum and hospital administration. While at Netley they will also undergo a course of instruction in company and ambulance drill and in other military duties.

Pay and Allowances §

The rate of pay drawn by Lieutenants from the date of passing the final examination at the Army Medical School until arrival in India is 10s a day

Pay at the above rate is issued in this country up to the date of embarkation and an advance of two months pay at the same rate is also made prior to embarkation, which is adjusted in India.

The following are the rates of Indian pay and allowances" which will be drawn by officers hereafter appointed to the Indian Medical Service —

Rank	Years service	Indian pay and allowance per mensem	
		When not holding an appointment carrying higher pay	
		Rs a. p	
Lieutenant-Colonel (Senior)		900 0 0	
Lieutenant-Colonel	25 and over	888 12 0	
Lieutenant Colonel	20 ,,	852 3 7	
Major	15 ,,	677 6 11	
,,	12 ,	640 14 6	
		A When not receiving any staff allowance	B When receiving staff allowance in addition
		Rs a p	Rs a p
Captain	10 ,	500 0 0	450 0 0
	5 ,,	450 0 0	400 0 0
Captain and Lieutenant	under 5	350 0 0	300 0 0

On first appointment they will only come into receipt of "Indian pay and allowances from the date of their arrival in India

Officers holding the principal administrative appointments and substantive military charges of the Indian Medical Service receive at present the following consolidated salaries —

		Rs per mensem
Surgeon General		2700 to 2200
Colonel ..	from	2250
	to	1800
Lieutenant Colonel in substantive charge of a native regiment		1000 or 1100 with Rs 90 horse allowance in cavalry regiments
Major in substantive charge of ditto		800 with Rs 90 ditto
Captain above 5 years' full pay service in substantive charge of a native regiment		600 with Rs 60 ditto
Captain or Lieutenant under 5 years ditto in substantive charge of a native regiment		450 with Rs 60 ditto

The salaries of other substantive medical appointments in the Civil and Military Departments are consolidated and vary from Rs 1800 to Rs 400 per mensem

Medical charges are of two kinds—substantive and officiating The first is held by an officer as his fixed permanent appointment For this he is entitled to the monthly consolidated pay as above shown An officiating charge is held by an officer who is acting temporarily in an appointment during the absence of an officer whose substantive charge it is The officer thus officiating receives not the consolidated pay of the appointment but the Indian pay allowance of his own grade plus half the staff pay of the appointment in which he is officiating (plus half the staff pay of his own appointment if he have one) The staff pay of an appointment is the difference between the Indian pay and allowances and the consolidated pay of the permanent incumbent The extra allowance for an officiating charge cannot be less than Rs 100 a month

Qualified officers of the Medical Service are also eligible for appointments in the Assay Department The salaries of these appointments are from Rs. 600 to Rs 2250 per mensem

Officers are required to perform two years regimental duty in India before they can be considered eligible for civil employment

Except in the administrative grades and in certain special appointments officers are not debarred from taking private practice as long as it does not interfere with their proper duties

Under present arrangements officers who are not statutory natives of India receive exchange compensating allowance, to compensate them for the fall of the value of the rupee The allowance consists of an addition to their salaries equal to half the difference between their salaries converted at (1) 1s 6d the rupee and (2) the average market rate for each quarter

Tenure of Office in Administrative Grades

The tenure of office of Surgeon Generals and Colonels is limited to five years

Colonels if not disqualified by age are eligible either for employment for a second tour of duty in the same grade or for employment in the higher grade of Surgeon General by promotion thereto

Absence on leave in excess of eight months during a five years tour of duty involves forfeiture of appointment

Surgeon Generals and Colonels on vacating office at the expiration of the five years tour of duty, are permitted to draw *in India* an unemployed salary of Rs 1200 per mensem in the former, and Rs 900 in the latter case for a period of six months from the date of their vacating office after which they are placed while unemployed on the following scale of pay

—	Surgeon General Per diem	Colonel Per diem
	£ s d	£ s d
After 30 years service on full pay	2 5 0	1 14 0
,, 25 , , ,,	2 5 0	1 10 0
,, 20 , , or on promotion should this period of service not be completed	2 0 0	1 8 0

A Surgeon General or Colonel who has completed his term of service and has reverted to British pay may reside in Europe at the same time qualifying for higher pension

Retiring Pensions and Half Pay

Officers of the Indian Medical Service will be allowed to retire on the following scale of pension, on completion of the required periods of service —

After 30 years service for pension	£700 per annum + £350 after five years' active employment in India as a Surgeon General or + £250 per annum after five years active employment as a Colonel
,, 25 ,, ,, ,,	£500 per annum
,, 20 , , ,,	£365 ,
,, 17 ,, ,, ,,	£292 ,,

Time (not exceeding one year) passed on temporary half pay reckons as service for promotion and pension in the case of an officer placed on half pay on account of ill health contracted in the performance of military duty

Officers of the Indian Medical Service are liable after retirement on pension before completing 30 years service to recall to military duty in case of any great emergency arising up to 55 years of age

All officers of the rank of Lieutenant-Colonel and Major are placed on the retired list at the age of 55 and all Surgeons General and Colonels at the age of 60

Officers not entitled to pension when placed on temporary or permanent half pay, will be granted the British rate of half pay of their military rank, as under :—

Rank	Rates of Half pay ‖	
	Per diem.	Per annum
	s d	£ s d
Lieutenant-Colonel (Senior) Lieutenant-Colonel	11 0	200 15 0
Major	9 6	173 7 6
Captain	7 0	127 15 0
Lieutenant	3 0	54 15 0

Invalid Pensions

An officer who has become incapacitated for further service in India on account of unfitness caused by duty may after he has been two years on temporary half pay, be granted an Invalid Pension on the following scale —

	Per annum
After 16 years pension service	£272
, 15 , ,	252
, 14 , , ,,	232
, 13 , ,	212
12 , ,	192

Wound Pensions

Officers are entitled to the same allowances on account of wounds and injuries received in action as are granted to combatant officers of His Majesty's Indian Military Forces holding the corresponding military rank

Family Pensions

The claims to pension of widows and families of officers are treated under the provisions of such Royal Warrant regulating the grant of pensions to the widows and families of British officers as may be in force at the time being

The widows and families of officers are also entitled to pensions under the Indian Service Family Pension Regulations, for the benefits of which all officers must as a condition of their appointment subscribe from the date of their arrival in India

Honours and Rewards

Officers of the Indian Medical Service are eligible for the military distinction of the Order of the Bath and for other Orders British and Indian and for good service pensions Six of the most meritorious officers are named Honorary Physicians and six are named Honorary Surgeons to His Majesty On appointment as Honorary Physician or Surgeon an officer below the rank of Colonel is promoted to that rank remaining supernumerary until absorbed

---

§ No staff or regimental allowance can be drawn until the lower standard examination in the Hindustani has been passed As many lieutenants have been sent to the frontier immediately on arriving in India they have found it impossible to study and pass this examination and have consequently been doing regimental and other work for Rs 350 a month Lately a concession has been granted to medical officers so situated on the frontier, but the rule is still most illiberal and requires alteration

‖ Officers cannot retire *in India* on half pay (No 45, Feb 28th 1865) (This is a rule that should be abolished)

PUBLIC HEALTH

INSTRUCTION FOR DIPLOMAS IN STATE MEDICINE.

ENGLAND

THE following recommendations, designed with a view of ensuring 'the possession of a distinctively high proficiency scientific and practical in all the branches of study which concern the public health," were adopted by the General Medical Council in 1902. The regulations require that—"(1) A period of not less than twelve months shall elapse between the attainment of a registrable qualification in Medicine Surgery and Midwifery and the examination for a diploma in Sanitary Science Public Health, or State Medicine, (2) every candidate shall have produced evidence of having attended after obtaining a registrable qualification during a period of six months, practical instruction in a laboratory British or foreign, approved of by the body granting the qualification and in which chemistry bacteriology and the pathology of diseases of animals transmissible to man are taught (3) every candidate shall have produced evidence that after having obtained a registrable qualification, he has for six months practically studied the duties, routine and special of Public Health administration either under a medical officer of health who is a teacher in public health in a recognised school, or in England under the medical officer of health of a county or of a single sanitary district of 50,000 or in one or more districts of 30 000 in Scotland or Ireland provided that the six months may be reduced to three if a candidate produces evidence that after obtaining a registrable qualification he has for three months attended a course of recognised instruction in sanitary law sanitary engineering vital statistics, and other subjects bearing on Public Health administration (4) every candidate shall produce evidence that after having obtained a registrable qualification he has attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration (5) the examination shall have been conducted by examiners specially qualified and shall comprise laboratory work as well as written and oral examination (6) the rules as to study shall not apply to medical practitioners registered, or entitled to be registered on or before Jan 1st, 1890 It was enacted by Section 18 (2) of the Local Government Act [England and Wales] 1888, that after Jan 1st 1892, no such appointment (that of medical officer of health) may be made in any county or in any district or combination of districts with a population of 50 000 or upwards, unless the officer—having of course, qualifications in Medicine, Surgery and Midwifery—is registered as the holder of a diploma in Sanitary Science, Public Health, or State Medicine under Section 21 of the Medical Act 1886 or has during any three consecutive years preceding 1892 been medical officer of a district or combination of districts with a population of 20 000 at least, or has for three years previously to August 13th 1888 been a medical officer or inspector of the Local Government Board With the sanction of the Local Government Board the same person may be appointed medical officer for two or more districts

The regulations in question as to study may be procured at the office of the General Medical Council in London

London University—Sanitary Science is included under the head of State Medicine in the M.D degree and a certificate has to be produced showing that a course of practical instruction has been attended for the prescribed period, and that the course has included such chemical, microscopical, and meteorological work and exercises as more especially relate to sanitation. The attendance includes six months practical instruction in a laboratory and six months outdoor sanitary work. Certificates will be received from the holder of any public health office directly or indirectly subject to control by a Secretary of State or a Government Department. Candidates for the M D degree in State Medicine must have (1) studied State Medicine for two years or (2) have studied State Medicine for one year and have held for a period of two years the position of medical officer of health in any sanitary district or (3) without having studied State Medicine have held for a period of three years the position of medical officer of health in any sanitary district

Cambridge University—Two examinations in so much of State Medicine as is comprised in the functions of medical officers of health will be held during the year 1902-3 in Cambridge Each examination will consist of two parts Part I will begin on the first Tuesday in April and October respectively Part II will begin on the second Tuesday in April and October respectively, and each part will end on the following Thursday Any person whose name is on the Medical Register is admissible as a candidate for this examination provided (1) a period of not less than twelve months shall have elapsed between the attainment of registrable qualification and the time when he presents himself for either part of the examination, (2) he produce evidence of having after obtaining a registrable qualification attended during three months the practice of a hospital for infectious diseases at which opportunities are afforded for the study of methods of administration (3) he produce evidence of having, after obtaining a registrable qualification attended during a period of six months on one or more courses approved by the Syndicate of practical laboratory instruction in Chemistry Bacteriology and the Pathology of those diseases of animals that are transmissible to man (4) he produce evidence of having after obtaining a registrable qualification for six months (of which at least three months shall be distinct and separate from the period of Laboratory instruction) been associated day by day in the duty routine and special of public health administration under the supervision of (*a*) in England and Wales either the medical officer of health of a county or of a single sanitary district having at the date of the last census a population of not less than 50 000 or the medical officer of health of a combination of two or more sanitary districts having collectively at the date of the last census a population of not less than 35 000 or (*b*) in Scotland or Ireland the medical officer of health of a county or of one or more sanitary districts having at the date of the last census a population of not less than 30 000 or (*c*) a medical officer of health who is a teacher in the department of public health of a recognised medical school A certificate of an assistant officer of health of a county or a large urban district may be accepted, provided the medical officer of health of a county or district consents to the assistant officer giving such instruction Any candidate who shall produce evidence that he has himself held an appointment as medical officer of health under conditions not requiring the possession of a special sanitary diploma shall be exempt from this regulation The provisions as to previous study shall not apply to medical practitioners registered, or entitled to be registered, on or before Jan 1st 1890 The first part of the examination will have reference to the general principles of sanitary science and will comprise the following subjects The elements of chemistry and physics methods of chemical analysis and in particular the analysis of air and water The laws of heat and the elements of pneumatics hydrostatics, and hydraulics in their application to warming ventilation water supply and drainage The geological and other conditions determining the healthiness of sites for dwellings Sources storage, and purification of water-supply The elements of meteorology in relation to health Principles of building construction in their application to dwellings hospitals and schools The disposal of sewage and refuse and the general principles of sanitary engineering Disinfectants their chemistry and use The chemical and microscopical examination of foods and the detection of the commoner forms of contamination The methods of bacteriological investigation and analysis The bacteriology of air water food and soil The general pathology of infection and of the diseases of animals that are transmissible to man The second part of the examination will have reference to State Medicine and to the applications of Pathology and Sanitary Science, and will comprise the following subjects Laws and Statutes relating to Public Health[1] The model by laws of the Local Government Board Sanitation of dwellings, schools factories, and workshops, and of villages and towns Inspection of slaughter houses cowsheds &c Inspection of meat and other articles of food General epidemiology with special reference to the origin pathology symptoms prevention geographical distribution, and prevention of the epidemic, endemic and other infective diseases both of temperate and of tropical climates The methods applicable to the medical investigation of epidemics Effects on health of over crowding, vitiated air, impure water, polluted soils, and bad or insufficient food Unwholesome trades and occupations, and the diseases to which they have rise Nuisances injurious or dangerous to health The effects on health of season and climate. The principles and methods of vital statistics in relation to public health. (N B —The foregoing schedule is not to be understood as limiting the scope of the examination, which will include every branch of sanitary science No candidate will be approved by the examiners who does not show a high proficiency in all the branches of study, scientific and practical, which bear upon the duties of medical officers of health) The examination in both parts will be oral and practical as well as in writing One day at least will be devoted to practical laboratory work and one day to oral and practical examination in, and reporting on, subjects connected with outdoor sanitary work Candidates may present themselves for either part separately or for both together at their option , but the result of the examination in the case of any candidate will not be published until he has passed to the satisfaction of the examiners in both parts Every candidate will be required to pay a fee of £6 6*s* before admission or re admission to *either part* of the examination, but candidates who have presented themselves before the year 1896 will be re admitted to either part on payment of a fee of £5 5*s* Every candidate who has passed both parts of the examination to the satisfaction of the examiners will receive a diploma testifying to his competent knowledge of what is required for the duties of a medical officer of health All applications for information respecting this examination should be addressed to Dr Anningson, Walt-ham-sal Barton road, Cambridge, Secretary to the Syndicate Candidates who desire to present themselves for the examination must send in their applications on forms supplied for the purpose and transmit them with the fees to J W Clark M A., Registrary, University of Cambridge, for the April examination on or before March 17th and for the October examination on or before Sept 15th The prescribed certificates must be sent to the Registrary so as to reach him not later than 10 A M on March 29th and Sept 27th respectively Cheques should be crossed "Barclay and Co , Ltd " The fee for either part of the examination cannot be returned to any candidate who fails to present himself, but he will be entitled, without an additional fee, to be a candidate on one subsequent occasion Candidates must before admission to either part of the examination produce evidence of having satisfied provisions (1), (2), and (3), and before admission to Part II having satisfied provisions (4), above mentioned The following is a list of colleges and schools of medicine at which the courses of laboratory instruction have, for the purposes of this examination, been already approved by the State Medicine Syndicate The Chemical and Pathological Laboratories Cambridge , the London Hospital Medical College , St Bartholomew's Hospital Medical College , King's College, London , University College, London , the Army Medical School, Netley , Owens College, Manchester , the University of Durham Medical School, Newcastle on-Tyne , Mason College, Birmingham , University College and Southern Hospital School, Liverpool, St Mary's Hospital Medical College , Charing cross Hospital College , Westminster Hospital Medical School, University College, Bristol , Yorkshire College, Leeds , Guy's Hospital Medical School , St Mungo's College, Glasgow , Edinburgh University Public Health Laboratory , Middlesex Hospital Medical School , Royal Southern Hospital, Liverpool , Royal Colleges, Edinburgh , Surgeons' Hall, Edinburgh , British Institute of Preventive Medicine , Trinity College, Dublin , Queen's College, Belfast , St Thomas's Hospital Medical School , University College, Cardiff , University College, Sheffield , and Medical School, Catholic University, Dublin

---

[1] All candidates will be examined in the provisions of the English Statutes relating to public health but any candidate will be given an opportunity of showing a special knowledge of other sanitary laws in operation within the British Empire, provided that [illegible] [illegible] [illegible] to the examiners [illegible] [illegible] the special law he proposes to offer

University of Oxford (Diploma in Public Health) —An examination, open to all registered medical practitioners, conducted partly in writing, partly *vivâ voce*, and in each subject partly practical, is held in Michaelmas Term in the following subjects —General Hygiene, General Pathology (with special relation to Infectious Diseases), the Laws relating to Public Health, Sanitary Engineering, Vital Statistics The fee for admission to the examination is £10 The names of candidates must be sent on or before Nov 8th to the Secretary to the Boards of Faculties, to whom applications for any further information should be made

University of Durham —Sanitary Science is the special object of the degrees in Hygiene Candidates for the degree of Bachelor in Hygiene (B Hy) must be at least twenty two years of age, registered, and a graduate in Medicine of a recognised university, and at least twelve months shall have elapsed after the date when the candidates obtained their first registrable qualification in Medicine, Surgery, and Midwifery before presenting themselves for examination They shall spend six months at Newcastle upon Tyne studying Comparative Pathology, Practical Bacteriology, Outdoor Sanitary Work, Infectious Diseases, Sanitary Chemistry, and Physics. They have to pass an examination in Sanitary Chemistry, Physics, Comparative Pathology, Sanitary Legislation, Vital Statistics, Nosology, Climatology, Meteorology, Distribution of Health and Disease, Sanitary Medicine and Practical Hygiene The fee for the examination for the degree of B Hy is 10 guineas, and for the degree £6 6*s* The examination is divided into two parts and candidates may present themselves for either part or both together at their option Candidates for the degree of Doctor in Hygiene (D Hy) must have acquired the degree of Bachelor in Hygiene, must for two years subsequently have been engaged in practice as a medical officer of health and must write an essay upon some practical hygienic subject The fee for the examination for the degree of D Hy is £5, and for the degree £6 6*s* The regulations for education and examination for the Diploma in Public Health (D P H) are the same as those for the degree of Bachelor of Hygiene, except that the candidate is not required to be a graduate in Medicine of a recognised University, and the course of study need not be passed at Newcastle upon Tyne The fee for the examination and Diploma in Public Health is 10 guineas

Victoria University —An examination in Public Health is held yearly under the following regulations The examination is in two parts, and is written, oral, and practical Candidates before entering for either part of the examination must have held for not less than twelve months a registrable qualification in Medicine, Surgery and Midwifery, and must present satisfactory certificates of having attended courses of instruction in Public Health in a college of the University, or in a college or medical school recognised for this purpose by the University , of having attended, after obtaining a registrable qualification, during at least six months, practical instruction in a laboratory approved by the University, the courses including Chemistry as applied to Public Health, Bacteriology, and the Pathology of those diseases of animals which are communicable from animals to man , of having attended for three months the clinical practice of a hospital for infectious diseases , of having practically studied the duties of outdoor sanitary work for not less than six months under the medical officer of health of a county or of a large urban district Candidates may present themselves for Parts I and II separately or at the same time, provided that no candidate be admitted to Part II unless he has already passed in Part I No candidate's name will be published until he has satisfied the examiners in both parts of the examination The fee for each part is £5 5*s* , and must be paid on or before July 1st in each year For any subsequent examination in the same part the fee will be £3 3*s* Every candidate who has passed both parts of the examination to the satisfaction of the examiners, and who is legally registered, will receive a Diploma in Public Health The examinations will begin on the third Monday in July each year

Royal College of Physicians of London and the Royal College of Surgeons of England — The following are the regulations for obtaining the Diploma in Public Health Section 1 Candidates must be registered under the Medical Act The examination consists of two parts The fee for each part is £6 6*s* A candidate intending to present himself must give fourteen days' written notice to the Secretary, at the Examination Hall, Thames Embankment, W C A candidate registered under the Medical Act on or before Jan 1st, 1890, will be admissible to Part I of the examination on producing evidence of being at least twenty three years of age, and to Part II. on producing evidence of being at least twenty-four years of age A candidate registered under the Medical Act after Jan 1st, 1890, will be admissible to examination in Part I on producing evidence (1) of having been in possession of a registrable qualification in Medicine Surgery and Midwifery for at least twelve months (2) of having attended, after obtaining such registrable qualification practical instruction in a laboratory recognised by the Examining *Board in England during* a *period of six months* and (3) of being at least twenty three years of age A candidate will be admitted to Part II of the examination on producing evidence (1) of having been associated day by day in the duty routine and special of Public Health administration during six months (of which at least three months shall be distinct and separate from the period of laboratory instruction required under Par 2 for Part I) under the supervision of a medical officer of health who fulfils certain conditions which can be ascertained on application to the secretary (2) of having attended the clinical practice of a hospital for infectious diseases recognised by the Examining Board in England after obtaining his registrable qualification in Medicine, Surgery and Midwifery and (3) of being at least twenty four years of age.

King's College London — The necessary Laboratory Instruction to comply with the regulations of the various Universities and other Medical Licensing Bodies will be given by Professor William R. Smith, M D D Sc and Professor Hewlett, M D Lond The syllabus includes Physics Chemistry Microscopy, Parasites and other Organisms Infesting Food stuff or the Human Body Bacteriology including the Cultivation and Recognition of Micro-organisms The course will last six months, four months of which will be spent in the Laboratories of Public Health, and two months in the *Bacteriological Laboratory Fee 20 guineas* payable in advance in the College office Under the direction of Professor William R. Smith, M D D Sc., and Demonstrator E Russell B Sc. F C S., practical instruction will be given in the laboratories in the methods of Analysis of Air Water Foods &c., Detection of Poisons. Fees, one month £4 4*s*, three months, £10 10*s* The laboratories are also available for original investigations and practical work in Public Health and are open daily from 9 A.M to 4 P M. and on Saturdays to 1 P M In Public Health special classes will be held during the winter session by Professor W R Smith fee, £12 12*s* The Bacteriological Laboratory is open daily for original research under the direction of the professor and demonstrator of General Pathology and Bacteriology For one month for original research 5 guineas For a longer period by arrangement. For one month for private study with supervision 5 guineas For a longer period by arrangement Practical course for a month with attendance on lectures 5 guineas For a year 30 guineas. Professor H G Seeley F R S. will deliver a *course of six lectures on* Physiography

University College Bristol —A course of lectures on the Principles and Practice of Hygiene is given at the College by D S. Davies M D Lond. D P H Cantab on Mondays and Fridays, 10–11 A M., commencing on the first Monday in October A six months course of Practical Laboratory Instruction is given at the Western Counties Laboratory Park street, by Mr F Wallis Stoddart commencing on the first Wednesday in October and including the subjects of Chemistry and Physics Instruction in Bacteriology is given at the College by Professor A. F Stanley Kent, M.A. F L.S F G S Demonstrations on the provisions and practical working of the various Acts relating to Public Health and on the Orders Circulars, and By laws of the Local Government Board are delivered by Mr J C Heaven on Mondays and Fridays commencing on the first Monday in October Gentlemen taking out the course are admitted to practical outdoor sanitary work during the session under the supervision of the medical officer of health for the city and port of Bristol They are considered as pupil assistants and are required to carry out diligently such of the duties of medical officers of health as they may be directed to undertake Facilities are afforded during the course for the study of those diseases of the lower animals which are communicable to man Fee for the entire course 30 guineas

University of Birmingham —The University grants a degree of B Sc in Public Health and also a Diploma in the same subject on the following conditions Graduates in Medicine of this University may become candidates for the degree of Bachelor of Science in Public Health by conforming to all the requirements laid down for candidates for the Diploma in Public Health except that after graduating in Medicine all courses of study must be taken out in the University and they must in addition have attended a three months course of Geology in the University The following are the regulations for Diploma in Public Health (general conditions) —1. All candidates must be registered under the Medical Act 2 The examinations will be held in the months of January and June and will consist of two parts No candidate will be allowed to pass Part II until he has passed Part I 3 Candidates may enter for Parts I and II separately or at the same time 4 The examination in each part will be written oral and practical 5 Candidates intending to present themselves for either part of the examination must give 14 days notice in writing to the registrar of the University 6. The fee for each part of the examination is £5 The conditions of admission to the examinations are identical with those recently approved by the General Medical Council

SCOTLAND

Edinburgh University —Two degrees in Science in the Department of Public Health are conferred by the University of Edinburgh, viz. Bachelor of Science in Public Health and Doctor of Science in Public Health Candidates for the degree of B Sc in Public Health must be graduates in Medicine of a University of the United Kingdom, or of some other University recognised for the purpose and must pass two examinations for the first of which they must, after graduation in Medicine have worked for at least twenty hours per week during a period of not less than eight months of which at least five consecutive months must be in the *Public Health Laboratory of the University of Edinburgh* and the remainder either there or in a laboratory recognised by that University they must also have attended lectures on Physics and Geology in some Scottish University Candidates are not admitted to the Second Examination sooner than six months after having passed the First Examination nor sooner than eighteen months after having taken their degree in Medicine and they must have attended two separate courses in Public Health in some University of the United Kingdom or in such medical school or Indian Colonial or Foreign University as may be approved for the purpose by Edinburgh University each course consisting of forty lectures at least one of these courses shall deal with medicine and the other with engineering each in its relation to public health They must also give evidence (1) that for six months they have practically studied sanitary work under the medical officer of health of a county or borough or district containing a population of not less than 25 000 (2) that they have had three months clinical instruction regarding *fevers* and infectious diseases and (3) that they have had three months instruction in mensuration and drawing The subjects of examination include Laboratory work Physics, Geology Medicine in its application to Public Health, Sanitation, Sanitary Law and Vital Statistics Graduates who have held the degree of B Sc in Public Health from the University of Edinburgh *for a term of five* years may offer *themselves for the degree of* D Sc in Public Health in that University They must then present a Thesis and pass an examination in Public Health. The *fees* are £3 3*s* for the First and £3 3*s* for the Second B Sc Examinations and £10 10*s* for the degree of D Sc.

University of Aberdeen —The Diploma in Public Health (D P H.) is conferred only on graduates in Medicine of a University in the *United Kingdom and a period of not less* than twelve months must elapse between medical graduation and entrance to the examination for the diploma Every candidate must produce evidence of having attended after graduation in Medicine during a period of six months, practical instruction in Hygiene and Bacteriology in laboratories approved of by the University together with having during six months (whereof three months must be distinct from the period of laboratory instruction) been associated day by day in the duties of Public Health administration under the medical officer of health of a county or large urban district He must also have regularly attended for six months the wards of a general fever hospital containing not less than fifty beds Every candidate who is not a graduate in Medicine of this University must have attended a course of instruction in the University in one or more of the subjects embraced in the examination for the diploma The diploma is conferred after an examination in Public Health held in March and July [illegible] each year Candidates desiring to appear for examination at either of these periods must send in their names with the necessary fee, to the Secretary of the Medical Faculty a fortnight before the examination The fee is £5 5s The examination is conducted by specially qualified examiners appointed by the University Candidates may enter for the whole examination at one period or they may enter for Part I at one period and for Part II at another and subsequent period

The Royal Colleges of Surgeons and Physicians of Edinburgh and the Faculty of Physicians and Surgeons of Glasgow —All candidates for the Diploma in Public Health must have been qualified for at least one year Those qualified before 1890 do not require to produce evidence of attendance on any special courses All other candidates must have attended, after qualifying, six months' practical instruction in a recognised public health laboratory or laboratories, and must have studied for six months the duties of outdoor sanitary work under the medical officer of health of a county or large urban district or a medical officer of health who is also a teacher of Sanitary Science in a Medical School, or must themselves have held an appointment as medical officer of health under conditions not requiring the possession of a sanitary diploma It is also recommended where possible to take out a course of instruction in the diseases of animals transmissible to man There are two examinations, and candidates may enter for both at one period or for either separately The First Examination includes (*a*) Laboratory Work (Chemistry and Bacteriology), (*b*) Physics, and (*c*) Meteorology, and the Second Examination embraces (*a*) Report on Premises visited, (*b*) Examination at Fever Hospital, (*c*) Examination at Public Abattoir, (*d*) Written and Oral Examinations on Epidemiology and Endemiology, (*e*) Vital Statistics and Sanitary Law, and (*f*) Practical Sanitation The fee is 12 guineas for both examinations, or 6 guineas for either of them A fee of £3 3s is payable by rejected candidates for either examination The examination is held twice yearly in May and October The published regulations provide detailed synopses of the subjects of examination and give lists of books from which to select The Registrar for Edinburgh is Mr James Robertson, solicitor, 54, George-square, and for Glasgow Mr Alexander Duncan, LL D, 242, St Vincent street

IRELAND

Royal University of Ireland —This University grants a Diploma in Sanitary Science. It is conferred only on graduates in Medicine of the University Candidates are not admitted to this examination until the lapse of twelve months from the time of obtaining the first registrable qualification, they must give notice in writing to the Secretaries of their intention to present themselves and must pay the fee, £2 at least one month previously to the examination Candidates are required to produce a certificate of having, after obtaining the degrees of M B, B Ch, B A O, attended six months practical instruction in a laboratory approved by the University, and also of having for six months practically studied the duties of outdoor sanitary work under the Medical Officer of Health of a county or large urban district Candidates at this examination must answer in the following subjects (1) Physics, (2) Climatology, (3) Chemistry (4) Microscopy, (5) Bacteriology, (6) Geology, (7) Sanitary Engineering, and (8) Hygiene, Sanitary Law, and Vital Statistics

University of Dublin —The Diploma in Public Health is conferred, after examination on the following conditions —The candidate must be a Doctor in Medicine or a graduate in Medicine, Surgery, and Midwifery of Dublin, Oxford, or Cambridge The name of the candidate must have been on the Medical Register at least twelve months before the examination The candidate must have completed (unless registered as a practitioner on or before Jan 1st, 1890), subsequently to registration, six months' practical instruction in a laboratory approved by the University and also have studied practically outdoor sanitary work for six months under an approved officer of health The subjects of examination will be —Part I Chemistry, Bacteriology, and Hygiene, Pathology (including methods of post-mortem examinations), Physics, and Meteorology Part II Hygiene and Epidemiology, Vital Statistics, Public Health Acts, Sanitary Engineering and Reports

Royal College of Physicians and Royal College of Surgeons in Ireland —Stated examinations for the Diploma in Public Health are held in the months of February, May, and November. A special examination for the diploma can be (except during the months of August and September) obtained on payment of £10 10s, in addition to the ordinary fees mentioned below, and on giving notice at least one fortnight before the date of the proposed examination Every candidate for the Diploma in State Medicine must be a registered medical practitioner (Candidates registered or entitled to be registered prior to January, 1890, are exempt from the rules as to study) He must subsequently to qualification (1) receive six months' laboratory instruction in Chemistry, Bacteriology, and the Diseases of Animals transmissible to man, and (2) during six months either practically study outdoor sanitary work under a medical officer of health or himself hold an appointment of medical officer of health under conditions not requiring the possession of a special sanitary diploma and shall as an additional requirement attend a hospital for infectious diseases, unless this has been already done during his ordinary medical course Candidates are examined on four days commencing on the first Tuesday of February, May, and November, Each candidate must return his name to the secretary of the Committee of Management under the Conjoint Scheme three weeks before the examination, and lodge with him a testimonial of character from a Fellow of either of the Colleges, or of the Royal Colleges of Physicians or Surgeons of London or Edinburgh The fee for the examination is £10 10s The examination for the diploma in State Medicine comprises the following subjects —State Medicine and Hygiene, Chemistry, Meteorology and Climatology, Engineering, Vital Statistics, Law and Bacteriology For further particulars apply to the Secretary, Committee of Management, Office, Royal College of Physicians, Dublin

DENTAL SURGERY

ANYONE who is on the Medical Register is entitled to practise as a dentist, although he cannot register as such without the special licence, but it is of eminent advantage to take the L D S, otherwise few dental appointments at general or special hospitals or dispensaries are available, and, what is still more important, the manual dexterity and knowledge of mechanics requisite for the successful practice of dentistry can only be gained by long and careful training at the dental operating chair and in the dental laboratory, and, this having been attained, it is but little trouble to pass the special examinations The subjects beyond those included in the general qualification are—Dental Anatomy and Physiology (Human and Comparative), one course, a separate course of Dental Histology, including the preparation of microscopical sections, Dental Surgery, one course, a separate course of Practical Dental Surgery, a course of not less than five lectures on the Surgery of the Mouth, Dental Mechanics, one course, a course of Practical Dental Mechanics, including the manufacture and adjustment of six dentures and six crowns, Dental Metallurgy, one course, a course of Practical Dental Metallurgy, Practice of Dental Surgery at a recognised school, two years, and a certificate of having been engaged during a period of not less than two years in acquiring a knowledge of Dental Mechanics (this may be obtained by apprenticeship to a duly qualified dental practitioner or in the mechanical department of a recognised dental hospital) The Dental Schools in London are the Dental Hospital of London, the National Dental Hospital and College, and Guy's Hospital Dental School Most of the large provincial towns have now dental hospitals A convenient arrangement by which the M R C S, L R C P, and L D S can be taken is as follows —The Preliminary Examination in General Education having been passed the student should become apprenticed to a qualified dentist and register as a dental and medical student (This instruction, however, may be taken prior to the date of registration as a dental student.) During his apprenticeship the student should receive instruction in Chemistry and Physics, Pharmacy and Elementary Biology, and pass in these subjects before entering the hospital (The foregoing constitute the First Examination) Having entered the hospital the student should attend the dental and general courses contemporaneously, and pass at the end of the second winter the Second Examination—namely, Anatomy and Physiology At the completion of his second year of study the Dental Examination should be passed

The student should then devote his time to general studies and pass the Third Examination When time permits it is advisable to attend the general hospital only until after the First and Second Examinations have been passed At this point a break may be made to admit of the completion of the dental curriculum and the passing of the examinations for the L D S diploma The best course, however is to entirely finish the curriculum for the M R C S and L.R.C P and then take the special Dental work. The regulations for the Dental Licence of the Royal Colleges of Ireland and Edinburgh and of the Faculty of Physicians and Surgeons of Glasgow are very similar to those of the English College The L D S can also be obtained alone

REGISTRATION OF DENTAL STUDENTS.

The registration of dental students is carried on at the Medical Council Office in London in the same manner as the existing registration of medical students, and subject to the same regulations as regards Preliminary Examinations Students who commenced their professional education by apprenticeship to dentists entitled to be registered or by attendance upon professional lectures before July 22nd, 1878 (when dental education became compulsory) are not required to produce evidence of having passed a Preliminary Examination. Candidates for a diploma in Dental Surgery must produce certificates of having been engaged during four years in professional studies and of having received three years instruction in mechanical dentistry from a registered practitioner One year a *bonâ fide* apprenticeship with a registered dental practitioner after being registered as a dental student, may be counted as part of the four years of professional study The three years of instruction in mechanical dentistry or any part of them may be taken by the dental student either before or after his registration as a student, but no year of such mechanical instruction will be counted as one of the four years of professional study unless taken after registration.

It is now necessary for anyone practising Dental Surgery in this country to register and no foreign qualifications are admitted

The Royal College of Surgeons of England grants a diploma in Dental Surgery under the following regulations, which apply to all candidates who have registered as dental students after Jan 1st, 1897 Candidates are required to pass three examinations the Preliminary Science Examination the First Professional Examination and the Second Professional Examination I Preliminary Science Examination —Before admission to this examination the candidate must produce a certificate of having received instruction (which may be taken prior to the date of registration as a dental student) at a recognised institution in Chemistry Physics and Practical Chemistry The examination consists of these subjects and is identical with Part I of the First Examination of the Examining Board in England *II* The First Professional Examination —The candidate must produce the following certificates 1 Of having been engaged during a period of not less than three years in acquiring a practical familiarity with the details of mechanical dentistry under the instruction (which may be taken prior to registration as a dental student) of a competent practitioner or under the direction of the superintendent of the mechanical department of a recognised dental hospital In the case of qualified surgeons evidence of a period of not less than two, instead of three, years of such instruction will be sufficient. 2. Of registration as a dental student by the General Medical Council. 3 Of having attended at a recognised Dental Hospital and School (*a*) a course of lectures on Dental Metallurgy (*b*) a course of Practical Dental Metallurgy (*c*) a course of Lectures on Dental Mechanics and (*d*) a course of Practical Dental Mechanics including the manufacture and adjustment of six dentures and six crowns Candidates may present themselves for the First Professional Examination after the completion of six months attendance at a recognised Dental Hospital and School The Examination consists of Mechanical Dentistry and Dental Metallurgy the examination in Dental Metallurgy will be by written paper III The Second Professional Examination —The candidate must produce the following certificates 1 Of having been engaged during four years in the acquirement of professional knowledge subsequently to the date of registration as a dental student. 2. Of having attended at a recognised dental hospital and school (*a*) a course of Dental Anatomy and Physiology, (*b*) a separate course of Dental Histology including the preparation of microscopical sections, (*c*) a course of Dental Surgery, (*d*) a separate course of Practical Dental Surgery, (*e*) a course of not less than five lectures on the Surgery of the Mouth, which lectures may be given at a dental hospital or at a recognised medical school; in the latter case they may form part of the course of lectures on Surgery (*f*) a course of Dental Materia Medica, and (*g*) a course of Dental Bacteriology, (*f*) and (*g*) will only be required of candidates who enter at a Dental Hospital on or after May 1st 1902. 3. Of having attended at a recognised dental hospital or in the dental department of a recognised general hospital the practice of Dental Surgery during two years 4 Of having attended at a recognised medical school (*a*) a course of lectures on Anatomy (*b*) a course of lectures on Physiology, (*c*) a separate Practical Course of Physiology (*d*) a course of lectures on Surgery and (*e*) a course of lectures on Medicine 5 Of having performed Dissections at a recognised medical school during not less than twelve months 6. Of having attended at a recognised hospital the practice of Surgery and *Clinical Lectures on Surgery during two winter sessions* 7 Of being twenty-one years of age The certificates of professional study will be required to show that students have attended the courses of professional study to the satisfaction of their teachers Candidates may present themselves for the Second Professional Examination after the completion of four years professional study from the date of registration as a dental student and after the lapse of not less than six months from the date of passing the First Professional Examination The Second Professional Examination consists of Part I. General Anatomy and Physiology General Surgery and Pathology, Part II Dental Anatomy and Physiology Dental Pathology and Surgery and Practical Dental Surgery The written examination in Part I. comprises General Anatomy and Physiology General Pathology and Surgery and in Part II Dental Anatomy and Physiology and Dental Pathology and Surgery At the Practical Examination candidates may be examined (*a*) on the treatment of Dental Caries, and may be required to prepare and fill cavities or to do any other operation in Dental Surgery (candidates must provide their own instruments) (*b*) on the Mechanical and Surgical Treatment of the various irregularities of Children s Teeth There is also an Oral Examination Candidates may take the two parts of the examination together or separately Exemption from the Preliminary Science Examination is granted to candidates who have passed an Examination in Chemistry and Physics for a degree in Medicine at a University in the United Kingdom, in India, or in a British colony Exemption from Examination in Anatomy and Physiology is granted to candidates who have passed the Second Examination of the Examining Board in England or the corresponding Examination of the Royal College of Surgeons of Edinburgh of the Royal College of Surgeons in Ireland or the Faculty of Physicians and Surgeons of Glasgow or of any University in the United Kingdom Exemption from Examination in General Surgery and Pathology is granted to candidates who have passed the Examination in Surgery of the Examining Board in England or the corresponding Examinations of the Colleges and Universities above mentioned The fee for the diploma is 20 guineas and is payable as follows:— Preliminary Science Examination, 3 guineas First Professional Examination, 2 guineas Second Professional examination 5 guineas the balance to be paid on the completion of the Examinations The Preliminary Science Examination is held in January March or April. July and October in each year The First and Second Professional Examinations are held in May and November in each year Candidates must give twenty-one clear days notice of their intention to present themselves for examination

Royal College of Surgeons Edinburgh —For the Licence in Dental Surgery all candidates must pass a Preliminary Examination in General Knowledge and have their names inscribed in the Register of Dental Students of the General Medical Council A copy of regulations giving a list of Preliminary Examinations recognised for obtaining this Licence as well as of the subjects of the Professional Examinations, may be obtained from Mr James Robertson, Clerk to the Royal College of Surgeons, at 54 George-square, Edinburgh. Students who commenced their professional education by apprenticeship or attendance on lectures before July 22nd, 1878, are exempt from the Preliminary Examinations Candidates must produce certificates of having, subsequently to the date of registration, been engaged for four years in professional studies and of three years' instruction in Mechanical Dentistry from a registered dental practitioner, except in the case of previously registered medical practitioners, when two years will be considered sufficient Candidates who have commenced their studies *after* Oct 1st, 1890, must have attended the following curriculum Anatomy, one course of six months, Practical Anatomy, twelve months, Chemistry, one course of six months, Practical Chemistry, one course of three months, Physiology one course of six months, Materia Medica, one course of three months, Surgery, one course of six months, Medicine, one course of six months, and attendance on the practice of a recognised general hospital, with Clinical Instruction, twelve months (Candidates who commenced study in accordance with the regulations in force before July, 1895, shall not be required to attend more than six months' hospital work) These courses must have been attended at a University or in an established school of medicine or in a provincial school specially recognised by the College as qualifying for the diploma in Surgery In addition to these courses candidates will be required to have attended in a recognised dental hospital, or with teachers recognised by the College, the following special courses of lectures and instruction Dental Anatomy and Physiology (Human and Comparative) (not less than 24 lectures), Dental Surgery and Pathology (not less than 20 lectures), Dental Mechanics (not less than 12 lectures)—one course each, two years' attendance at a dental hospital or the dental department of a general hospital recognised by the College Certificates of attendance on such of these courses of the new curriculum as may be respectively required will entitle candidates to appear either for the First Dental Examination or for the First and Second Examinations for the Triple Qualification, as they may select, and subject to the existing regulations for each qualification Candidates who have passed the First and Second Examinations for the Triple Qualification will be exempt from the First Dental Examination and will have the advantage of being admissible either to the Final Dental Examination or to the subsequent Examination for the Triple Qualification, or to both But the First Dental Examination will not be held as equivalent to the First and Second Triple Examinations and will admit to the Final Dental Examination only Candidates who are Licentiates of this College or who may be registered medical practitioners will be required to produce certificates of attendance on the special subjects only and will be examined in these only for the dental diploma First Professional Examination The candidate must have attended the courses on Anatomy, Chemistry, and Physiology The examination embraces Anatomy, Chemistry, and Physiology The fee for those candidates who began study before Oct. 1st, 1896, is £4 4*s* Second Examination The candidate must have attended the remaining courses of the curriculum, must produce certificates showing that he is twenty one years of age, and must pay a fee of £6 6*s* The examination embraces Surgery, Medicine, Therapeutics, and the special subjects of Dental Anatomy and Physiology, Dental Surgery and Pathology, and Dental Mechanics with Dental Metallurgy Unsuccessful candidates will be repaid £2 2*s* in the First and £3 3*s* in the Second Examinations Candidates who claim exemption from the First Dental Examination on the ground of having passed the First and Second Triple Qualification Examinations will, before being admitted to the Second Dental Examination, be required to pay the total fee of £10 10*s* payable for the dental diploma, of which £3 3*s* will be returned in case of rejection The fee payable by candidates who began study after Oct 1st, 1896, shall be £15 15*s*

Faculty of Physicians and Surgeons of Glasgow—The regulations as to certificates, curriculum, number, and subjects of examinations, fees, &c, are in effect similar to those of the Royal College of Surgeons of Edinburgh Special provision is made for candidates who intend to qualify both in Medicine and in Dentistry Candidates can enter for the First Examination in two divisions, the first embracing Physics and Chemistry, and the Second Anatomy and Physiology There is a practical examination in Mechanical Dentistry and also an examination in Practical Dentistry conducted in a dental hospital

Royal College of Surgeons in Ireland—All information concerning the licence in Dentistry may be obtained from the Registrar of the College, who will receive the applications of candidates for permission to be examined The bank receipt for fees, together with all certificates, &c, are to be lodged with him at least seven days prior to the day fixed for the commencement of the examination The Primary Dental Examinations commence on the second Monday in the months of February, May, and November The Final Dental Examinations commence on the Thursdays immediately following the Primary Dental Examinations Candidates are required to pass three examinations—viz., Preliminary (in General Education), Primary Dental, and Final Dental Preliminary Examination.—All examinations in general education recognised by the General Medical Council are accepted by the College Preliminary Examinations are held conjointly by the Royal Colleges of Physicians and Surgeons on the third Wednesdays in March and September Primary Dental Examination —Fee £10 10*s*; for re-examination, if rejected, £5 5*s* Every candidate[1] is required, before admission to the Primary Dental Examination, to produce evidence—(1) of having passed a recognised preliminary examination and of having been registered as a medical or dental student by the General Medical Council, (2) of having, subsequently to registration as a dental or medical student, attended at a recognised medical school the following courses Lectures on Practical Anatomy, including Dental Anatomy, six months, Demonstrations and Dissections, two courses of six months each, Lectures on Chemistry, six months, Lectures on Physiology, including Dental Physiology, six months, Practical Histology, and Practical Chemistry, including Metallurgy, three months, (3) of having attended Clinical Instruction at a recognised general hospital for one year The subjects of this examination are (1) Physics,[2] (2) Chemistry, including Metallurgy, (3) Anatomy, (4) Physiology and Histology, and (5) Surgery Final Examination —Candidates holding L R C S I or students who have passed Primary Dental or Third Professional Examination of the College, £10 10*s*, re-examination, £5 5*s* Fees for Final Examination of all other candidates, £26 5*s*, re-examination, £10 10*s* Extra fee for Special Examination, £5 5*s* Candidates must produce evidence of having passed the Primary Dental Examination of this College, or the Third Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall, or an equivalent examination recognised by the College, and are required to produce certificates of having attended (1) the following courses of lectures recognised by the College Dental Surgery and Pathology (two courses), Dental Mechanics (two courses), (2) for two years the practice of a dental hospital recognised by the College or of the dental department of a general hospital so recognised, (3) of having been engaged during four years in professional studies, and (4) of having received three years' instruction in Mechanical Dentistry from a registered dentist Candidates holding a diploma in Surgery shall be admissible to the Final Dental Examination on producing certificates of having attended (1) one course of Lectures on Dental Surgery and Pathology, (2) one course of Lectures on Dental Mechanics, (3) for one year the practice of a dental hospital recognised by the College, or of the dental department of a general hospital so recognised, where such attendance has been subsequent to the date of diploma (this remission (3) has been made on the understanding that the surgeon devotes his whole time to dental work), and (4) of having been engaged during a period of not less than two years in acquiring a practical familiarity with the details of Mechanical Dentistry under the instruction of a registered dentist The following are the subjects of examination Dental Surgery, Theoretical (including Dental Pathology), Clinical, and Operative, Dental Mechanics, Theoretical, Clinical, and Practical (including the Metallurgy of the Workshop) Examinations for the Licence in Dentistry *sine curriculo* The Council has power to admit to examination, *sine curriculo*, candidates whose names are on the Dental Register published under the direction of the General Medical Council and who are unable to furnish the certificates required by the foregoing regulations, on presentation of a special schedule of application.

---

[1] Candidates educated in England or Scotland are admitted to the Primary Dental Examination on the production of the certificates that would be necessary for both Primary and Final Examinations in their own countries

[2] Candidates who have passed in Chemistry and Physics at a First Professional Examination under the Conjoint Board with the Royal College of Physicians in Ireland, or with the Apothecaries' Hall or an equivalent examination recognised by the College, are exempted from examination in these subjects at the Primary Dental Examination.

TEACHING INSTITUTIONS.

ENGLAND

Royal Dental Hospital of London and School of Dental Surgery, Leicester-square.—The school provides the special dental education required by the Royal College of Surgeons for the Licence in Dental Surgery The general part of the curriculum may be taken at any general hospital. The hospital is open from 9 A.M. to 4 P.M. there being one staff for the morning and another for the afternoon of each day Pupils are received for the three years mechanical training recognised by the curriculum The demonstrators at the commencement of each session give a course of lectures on Operative Dental Surgery The eight house surgeoncies are held for one year each and are open to all qualified students The lecturers in addition to their lectures give special demonstrations on the *Microscopy of Dental Anatomy and Dental Surgery* The lecturer on Dental Mechanics also gives practical demonstrations in the mechanical laboratory Two scholarships of the value of £20 have been founded by Sir Edwin Saunders and Dr Joseph Walker The Storer Bennett Research Scholarship for Scientific Research in any branch of Dental Surgery value £50 is awarded triennially Prizes and certificates are awarded by the lecturers for the best examinations in the subjects of their respective courses, at the end of the summer and winter sessions A prize of the value of 5 guineas is given by Messrs Ash and Sons for the best essay on some surgical subject connected with Dental Surgery The conditions under which this prize is to be competed for are the same as those for the Saunders Scholarship with this exception that the papers are to be written in the hospital during the summer session. 	Sands Cox Scholarship.	£42.	3 years.	Awarded to the candidate not being more than 19 years of age taking the highest marks at the June Matriculation.	
	Dental Scholarship.	£37 10s.	3 years.	Open Competitive Examination in subjects learned during apprenticeship.	
VICTORIA UNIVERSITY ...	Gilchrist Scholarship.	£50.	3 years	Awarded annually to the candidate who shall stand highest at the June preliminary examination of the Victoria University provided that he pass in the first division	Candidates must be over 18 years of age on July 1st in the year of competition
	University Scholarship in Medicine.	£25.	1 year	Awarded annually on the results of the second examination for the degrees of M.B and Ch.B	
	University Fellowship in Medicine	£100.	1 year	Awarded annually for excellence and promise in one or more of the subjects of the Second or Final M.B Examinations	For the encouragement of Study and Research
OWENS COLLEGE MANCHESTER	General Entrance Scholarships.	——	——	——	Open to candidates above 16 and under 20 years of age
	Rogers	£40.	2 years.	Subjects: GREEK, LATIN TRANSLATIONS AT SIGHT and PROSE COMPOSITION	
	Seaton.	£40.	2 years.	Subjects GREEK LATIN TRANSLATIONS AT SIGHT and PROSE COMPOSITION	
	Dalton.	£40.	2 years	Subjects EUCLID ALGEBRA, TRIGONOMETRY GEOMETRY and CONIC SECTIONS.	
	Cartwright.*	£33.	3 years.	Ditto.	
	Hulme.	£35.	3 years.	Subjects ENGLISH LANGUAGE and LITERATURE, HISTORY GEOGRAPHY and LATIN GREEK FRENCH or GERMAN (any two subjects)	
	James Gaskill	£35.	3 years	MATHEMATICS MECHANICS and CHEMISTRY	
	Dora Muir †	£25.	3 years	Ditto	
	Manchester Grammar School.*	£18.	3 years.	MATHEMATICS, ENGLISH ESSAY with CLASSICS and PHYSICAL SCIENCE in alternate years	
	Kay-Shuttleworth.*	£30.	3 years.	Subjects as in James Gaskill Scholarships	Pupils of Sedbergh, Giggleswick or Burnley Grammar School.
	Theodores Exhibition	£15.	1 year	Subjects: FRENCH and GERMAN	Successful candidates are required to enter for a regular University course
	Robert Platt Physiological Scholarship.	£50.	2 years.	Subjects PHYSIOLOGY and COMPARATIVE ANATOMY	Open to Candidates whether or not previously students of the College
	Dauntesey Medical Scholarships (two).	£33 each.	1 year	Subjects: ZOOLOGY BOTANY and CHEMISTRY	These Scholarships are open to all students preparing for a Medical Course who shall not have attended Lectures or Laboratory Courses on Human Anatomy or Physiology, or a purely Medical or Surgical Course in the Owens College or any other Medical School in the United Kingdom. Candidates must not be more than 25 years of age on October 1st of the year of competition. Scholars must immediately upon election enter for a full course of medical studies.
	Robert Platt Exhibitions (two)	£15 each.	——	——	First and second year students in Physiology
	Sidney Renshaw Exhibition.	£15.	——	——	Second year students in Physiology
	Professor Tom Jones Exhibition in Anatomy	£25.	——	——	First year students in Anatomy

* Open to men candidates only

† Open to women candidates only

Annotations.

"Ne quid nimis"

UNIVERSITY OF LONDON

WE shall shortly publish an article dealing with the Faculty of Medicine of the University of London pointing out the extent to which the reconstitution of the University has modified the conditions of education and examination in the Faculty of Medicine.

HINTS TO MEDICAL VISITORS TO BERLIN

VISITORS to foreign cities usually find it helpful to know something of the experiences of those who have already traversed the same route, more especially when the objects of the journey are in each case the same, and an article entitled "Medical Notes from Berlin" contributed by Dr Donald Bremner Waters to the July number of the *Caledonian Medical Journal* contains passages which may be of interest to some of our readers. Dr Waters commences with the remark that Berlin is a very fine city where there is a great wealth of clinical material and the teaching is exceedingly good. Most of the clinics are held in the Charité Hospital or in its vicinity and large numbers of students occupy apartments in the immediate neighbourhood, so that the "Latin quarter" of Berlin may be said to form a circle with the Charité in the centre. There is not much difficulty in finding rooms for in certain parts of the city almost every house-door has a card with the announcement, "Hier ist ein Zimmer zu vermiethen." For those who prefer to reside in one of the suburbs in order to avoid the stir and bustle of the city proper Charlottenburg may be recommended as it is not too far from the clinics and better rooms may perhaps be obtained there at no higher rates than in the central localities. Charlottenburg is three or four miles from the Charité but there is an excellent train service with trains running every five minutes and a ticket for a month costs only three marks. In exchange value a mark is almost identical with a shilling but in general a mark will go further in Germany than a shilling will in Great Britain. The rent of one room in Berlin may be estimated at from 30 to 40 marks per month varying according to size and situation, and especially according to the floor on which the room is. Rooms on the first floor cost about double of those on the fourth. The landlady provides morning coffee for which she charges from six to eight marks, but dinner and generally supper must be obtained outside in one of the numerous restaurants where the prices are moderate, especially if the visitor knows exactly where to go. The more conversant the visitor is with German the more he will profit by the opportunities offered in the clinics, and for some it would probably be advisable that they should begin by living in a pension or family. There is a truly bewildering choice of clinics for in each of the important branches of medicine and surgery there are at least two courses in some cases more conducted either by the professors or by *privat-docents* while additional classes are held by others not so intimately connected with the university. If the visitor desires to obtain a certificate from the university that he has attended classes it is necessary to matriculate. This costs only something like 16*s.* and full value is got for the money as a number of short (though by no means unimportant) courses are thereby open to the matriculant without further fee. The fees for the various clinics are much lower than for the corresponding courses in Great Britain. As a rule they cost about 30 to 40 marks with the exception of practical classes such as bacteriology &c. which are somewhat dearer. There are two *semesters* in each year the winter *semester* from Nov 1st to the end of February and the summer one from May 1st to the end of July. In addition to the courses held in the two *semesters* there are Ferien-Curs (vacation courses) held in March and October. Dr Waters says that these offer special advantages to medical men there is a course in nearly every subject and as they are for qualified men they are essentially practical. The work of the clinics begins early in the morning and continues until late in the evening. Professor Olshausen commences his gynæcological operations at 7.45 A.M. and one of the medical clinics is held from 8 to 9 A.M. There are three medical clinics in Berlin conducted by Professor Gerhardt,[1] Professor von Leyden and Professor Senator respectively. Systematic lectures are not delivered the teaching being almost entirely clinical. The patient is brought before the students a short history of the case is given and two or three students who are detailed for the purpose investigate the case under the supervision of the professor who thereupon sums up and discusses the diagnosis. A similar procedure takes place at the polyclinics the only distinction being that more cases are discussed in the time. A point of difference between the German and British method is that in the former the students rarely come into the wards. There are special classes conducted by the *privat-docents* and the assistants of the clinic, in order to instruct students in physical signs and in the method of investigating cases.

THE Working Men's College 46 Great Ormond-street London W.C. has an ambulance class in connexion with the College. The present instructor is however unable to carry on the work during the coming session. We have been requested to publish an appeal for a volunteer and we do so with pleasure. The class meets once a week in the evening at an hour to be settled by the instructor. Communications should be addressed to the secretary Mr L. C Duchesne at the College.

THE report of the Principal Chemist of the Government Laboratory upon the work of the laboratory for the year ending March 31st 1902, has been published and we propose to deal with it in a future number.

POST GRADUATE STUDY

ASSOCIATION OF METROPOLITAN SCHOOLS OF MEDICINE.

ARRANGEMENTS have now been made by which the Association of the Metropolitan Schools of Medicine is enlarged so as to include (with one exception) all the institutions recognised by the University of London as seats of medical education. On and after Oct 1st next St. Bartholomew's Hospital and the five following special hospitals—the Brompton Hospital for Diseases of the Chest the Hospital for Sick Children Great Ormond street the London School of Tropical Medicine the National Hospital for the Paralysed and Epileptic and the Royal London Ophthalmic Hospital (late Moorfields)—become members of the association which already includes nine general hospitals. It is hoped that this widening of the scope of the association will have the effect of making it even more attractive in the future than it has been in the past. Amongst other privileges its ticket (the charge for which is 7 guineas for three months or 10 guineas for six months) will admit to the post graduate courses carried on at the hospitals both general and special which share in the scheme. By means of clinical lectures and demonstrations at which, so far as is possible patients are shown, the wealth of clinical material which would otherwise be almost unmanageable is made readily accessible. In connexion with the special departments of several of the general hospitals similar lectures and demonstrations will also be given at regular hours. Qualified men have thus placed at their disposal the best of all the hospital work in London.

---

[1] Since deceased.

This is a scheme of post-graduate instruction which should prove attractive above all others to graduate members of the metropolitan schools who wish to widen their ideas by observation of the methods of teaching and practice adopted at institutions other then their particular *alma mater*. The office of the Association remains as before at the Examination Hall, Victoria Embankment, W.C., where all information may be obtained between the hours of 12.30 and 3, except on Saturdays.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC.

This institution, of which Sir William Broadbent is President, affords to medical men special facilities for acquiring technical skill and for advancing their medical and scientific knowledge. The building contains lecture and consulting rooms, a pathological and clinical laboratory, a Roentgen ray room, an ophthalmoscope room, a museum, a library, and reading and writing rooms, &c. Clinical lectures are given each working day of the week except Saturday, at 4 P.M., and clinical lectures are given on alternate Wednesdays at 5.15 P.M. General and systematic lectures are given on special subjects twice a month. Classes are also held in practical bacteriology, mental diseases, hygiene and public health, and operative surgery. Extra classes in any subject are formed to suit the convenience of practitioners unable to attend those already provided. A complimentary ticket available for three successive days will be issued to any practitioner upon presentation of his visiting card. A monthly journal, the *Polyclinic*, recording the work done in the college, is issued free to subscribers and members. The annual subscription for practitioners residing in Great Britain and Ireland is one guinea and for practitioners non-resident in the United Kingdom half a guinea. Full information can be obtained from the Medical Superintendent at the college, 22, Chenies street, Gower street, W.C.

CHARING CROSS HOSPITAL.

Classes for post-graduate study are held on each Thursday of the week throughout the year at Charing Cross Hospital. The fee for each course of ten lectures is £1 1*s.* The first of the two winter courses this year will commence on Oct. 9th and will be conducted by the following members of the medical and surgical staff: Drs. Green, Bruce, Eden, Willcocks, Murray, and Galloway, and Messrs. Boyd, Waterhouse, Wallis, and Gibbs. Further information as to the dates and subjects can be obtained by communicating with the honorary secretary (Dr. Willcocks) at the hospital.

WEST LONDON POST GRADUATE COLLEGE: WEST LONDON HOSPITAL.

The West London Hospital, Hammersmith road, was the first general hospital in London to organise a systematic scheme for post graduate teaching and to devote the clinical material in its wards and out-patient department solely to the instruction of qualified men. The college was started in 1895, and three years later its basis was enlarged by the provision of accommodation for the post-graduates in the shape of lecture, reading, and writing rooms, &c., while owing to the continued growth of the college these were transferred last year to a building especially constructed for the purpose. The physicians and surgeons attend daily at 2.30 P.M. Post-graduates accompany the staff on their visits to the wards. Instruction is given in the out-patient department daily at 2.15 P.M. by the assistant physicians and assistant surgeons. The out-patient department has recently been enlarged and there is now ample accommodation for post-graduates to see and to examine the patients. There are special departments for Diseases of the Eye, the Ear, Throat, and Nose, the Skin, for Diseases of Women, Medical Diseases of Children, and for Orthopædic Surgery and for X-ray Work. Clinical Assistants are appointed from among the post-graduates. Practical classes for instruction in these subjects are held each session. They are limited in number and each member has opportunities of gaining experience in the methods of examination and treatment. Operations are performed on Mondays, Tuesdays, Wednesdays, Fridays, and Saturdays at 2.30 P.M. and on Thursdays at 3.30 P.M. Post-graduates are allowed to stand close to the table and can see the operations perfectly. The surgeons often avail themselves of the assistance of post-graduates at operations.

Instruction is given in the administration of anæsthetics by the anæsthetists on the operating days and post-graduates will be allowed to administer anæsthetics under their superintendence. Special classes are held each session, each will have opportunities of administering several different anæsthetics. Post-mortem examinations are performed at 5 P.M. and demonstrations on recent pathological specimens are given on Mondays and Fridays during each session, at 11 A.M. in the lecture room. Post-graduates also visit the wards in the mornings with the house surgeons and house physicians, they also often render assistance to these officers in the Casualty Department. Practical lectures and demonstrations are given each afternoon (except Saturday) at 5 P.M. during the session.

Fees.—The fee for the hospital practice, including all the ordinary demonstrations and lectures, is £1 1*s.* for one week, £2 2*s.* for one month, £4 4*s.* for three months, £6 6*s.* for six months, £9 9*s.* for one year, and £21 for a life ticket, all fees to be paid in advance. If it is wished to pay the fee by instalments the price of the yearly ticket will be £10 10*s.*, payable by one instalment of £4 4*s.* and two of £3 3*s.*, the first to be paid on joining, the second three months later, and the third at the end of six months, the fee for a life ticket will be £23 2*s.*, payable by four instalments of £4 4*s.* and two of £3 3*s.*, the first to be paid on joining, the second after three months, the third at the end of nine months, the fourth at the end of one year, and the two final ones at intervals of three months. A course of attendance on either the medical or surgical practice alone may be taken out for the fee of £3 3*s.* for three months. The fee for three months' attendance in any one special department other than medicine or surgery is £2 2*s.* for three months. Further information can be obtained on application to the Dean at the West London Hospital.

NORTH-EAST LONDON POST GRADUATE COLLEGE.

In connexion with the Tottenham Hospital, N., facilities are afforded to qualified medical men for taking part in the work of an active general hospital and of attending demonstrations of various branches of Medicine, Surgery, and Gynæcology with opportunities for other forms of clinical instruction, including Diseases of the Eye, Ear, Throat, Nose, Diseases of the Skin, and Dentistry. Clinical Lectures are given from time to time by members of the staff. Cases are demonstrated both in the wards and in the various out-patient departments, operations are performed every afternoon of the week except Saturday. The fee for a three months' course of study, which may be begun at any time, in any single department, is £1 1*s.* A fee of £2 2*s.* admits to the whole practice of the hospital for a similar term, and a perpetual ticket for the practice of the hospital may, for the present, be obtained on payment of a fee of £3 3*s.* Medical practitioners who have attended a three months' course in any department are eligible for appointment as Clinical Assistants in those departments. A certificate signed by the staff may be obtained at the end of three months' hospital attendance. Further information may be obtained from the Dean of the Post-Graduate College, Dr. A. J. Whiting, 142, Harley street, W.

METROPOLITAN EAR, NOSE, AND THROAT HOSPITAL.

This hospital, which is situated in Grafton street, Tottenham-court-road, gives facilities for post-graduate study. The fee for one month's attendance at the hospital is £1 1*s.* and for three months £2 2*s.* During the forthcoming session demonstrations will be given by the members of the staff on the pathology and treatment of diseases of the ear and respiratory passages. Short practical classes will also be held in clinical pathology and surgical anatomy of these regions. Weekly clinical lectures are given by the staff on the special diseases treated at the hospital, the time, date, and subject of these lectures are previously announced in the medical journals. These lectures are free to all medical practitioners and students.

PROVINCIAL POST GRADUATE STUDY.

The Liverpool School of Tropical Medicine in connexion with University College, Liverpool, provides post-graduate classes. Clinical instruction is given at the Royal Southern Hospital, which has a special ward for the reception and treatment of tropical diseases. In the pathological department of University College (Thompson Yates Laboratories) investigations of specimens may be made.

Ample facilities are provided at Cambridge University for post-graduate study and research in anatomy, physiology, pathology pharmacology and chemistry Lectures in clinical medicine and surgery are given at Addenbrooke s Hospital

Various courses of lectures are from time to time available for graduates at the Royal Infirmary of Edinburgh, the City Hospital and some other institutions.

Instruction in bacteriology and pathology is available for medical men throughout the year also at Belfast.

THE ARMY AS A MEDICAL CAREER

FEW matters of importance and interest to the medical profession, and especially to the medical student, have been more written about than the work and position of the Royal Army Medical Corps. After years of controversy between the Army Medical Service and various Governments we appear however to have reached at length a stage affording a more secure and satisfactory footing than has hitherto been the case. It cannot, we think, be denied that, as the result of the recent movement for the reform and reorganisation of the medical service of the army many radical and salutary changes and improvements have been effected in all that appertains to that service. We are very glad to be able to say this because we have always felt that on every ground it was highly undesirable that there should be among the younger members of the profession anything like a boycott of an important public service with distinguished traditions. The present time, therefore, affords a very fitting and favourable opportunity for taking accurate stock of the Army Medical Department and for frankly and dispassionately considering what are the inducements held out to young medical men to throw in their lot with the army and to serve their country and their profession by joining the Royal Army Medical Corps.

The medical service having some years ago been organised as a corps with an autonomy of its own and the question of the military titles, rank, and status of its officers having been settled in accordance with their wishes, and with those of the profession generally there still remained for solution the problems of how the needful supply of highly qualified medical candidates could be obtained and how the State could have the assurance that their scientific knowledge and professional efficiency would be always maintained.

The official answer to these questions is to be found in the last Royal Warrant published in THE LANCET of March 29th 1902, p. 912, and in the regulations for admission into the Royal Army Medical Corps which were published in THE LANCET of May 10th, 1902, p 1339 There is little need to refer to the fierce fire of adverse criticism which hailed the advent of the report of the War Office Committee. We said at the time that at that stage of the proceedings the report should be simply regarded as outlining an immature scheme, and that many of the objections would disappear when it came to be considered in detail as it would have to be, whilst it was being formulated officially into the shape of a warrant and regulations. This is what has actually taken place, and as regards the omission of all mention of India in the Royal Warrant we have since had the satisfaction of announcing the Secretary of State s decision that the warrant is to be made applicable to that country So far then as official documents are concerned all seems to be open and above board as regards the terms material advantages and conditions of service offered to intending candidates The medical officer of the future will be largely master of his fate. He will on entering the service be in possession of a fairly liberal rate of pay and will learn much that will be both new and interesting as well as much that will hereafter prove useful to him He will while serving in the corps have special opportunities for the study of his profession and can accelerate his promotion and qualify for an appointment with extra pay as an expert in subjects for which he has any special knowledge taste, or aptitude Success in the Army Medical Service is no longer by a dead level seniority the door is thrown open to professional merit and attainments in a way that has never before been but which we have always advocated should be, the case. With the increased facilities for professional and scientific study and the establishment of a staff medical college in London, the public medical services will be brought into close relations with the medical profession in civil life and medical officers will be able to avail themselves of the large and varied field of clinical material and hospital practice to be found in this metropolis. All this should prove for the mutual benefit of the State and the medical service. There is, then no reason why a really good stamp of men should not in future be attracted to the army nor any reason why they should not, with periodically recurring opportunities provided for study be able to maintain a high professional standard and to keep themselves abreast with the progress of modern medical knowledge and thought.

Lest it be thought that we lay too much stress upon this matter we would point out that the Royal Army Medical Corps must first and foremost be regarded as a scientific branch of the service if it is to maintain a high and respected position, and that on the mere ground of self interest the officers and men of the army are quick to find out those whom they can trust when sick or wounded They are naturally only too glad to avail themselves of the aid and skill of those who show that they are keenly interested in their profession and are ready to do all they can to support the position of such men if only in order to retain the benefit of their services. It is, after all, a matter of common sense and experience that this should be so Of course in this, as in every other walk in life, a man has to a large extent to make his own position by the exhibition of his personal qualities but if in addition to being professionally capable he is in mind and manner a self respecting gentleman it would be hard to find a better or more pleasant position in life than such a medical officer will occupy An officer of this stamp has always made and will so long as human nature remains what it is continue to make, many true friends in the army And if he takes part in a campaign and serves on a battle-field he will experience what the ties of comradeship mean, will see surgery on a big scale and otherwise will learn lessons which he will never forget. There are besides some other things which medical service in the army offers that cannot be found in any other career A medical man in the army is a cosmopolitan. He sees in the course of his service-life many lands and many different peoples and meets with many new and varied experiences as he travels through fresh fields, each of them presenting stimulating subjects for curiosity observation, or inquiry; he is afforded opportunities for studying disease under different aspects and in different climates and under a variety of conditions and if he is a lover of nature and has an open and intelligent mind or a taste for natural history he cannot fail in the course of his service to meet with a variety of interesting objects and situations which rarely, if ever fall in the way of the civil practitioner in this country He is a medical officer and has perforce duties other than medical to discharge but he has a fixed and, on the whole, fairly good income and knows not the carking care and anxiety attending monetary struggles in early professional life

There is of course, another side. Many hardships are inseparable from army life and foreign service but on these things there is no need to dwell as they must all be more or less obvious. It is, perhaps, worth mentioning that if in many respects the army medical officer has to encounter obstacles and difficulties in the study and pursuit of his profession which are not present in civil life he enjoys one advantage the medical officer in dealing with soldiers is dealing with men living in community under exactly the same conditions he knows all about their environment, their mode of life and their habits so that under such circumstances the observations made regarding a body of troops often partake very much of the nature of an experiment.

To sum up the whole matter we think, then, that for young and well trained medical men generally the army as a career offers many distinct advantages and that for a certain class of enterprising and observant man service in it holds out unique opportunities

CONGRESS OF MEDICAL ELECTROLOGY AND RADIOLOGY.—The Second International Congress of Medical Electrology and Radiology will be held in Berne Switzerland, from Sept. 1st to the 6th. The proceedings will commence on August 31st with a reception at the Restaurant du Musée. The meetings will be held at the Institute of Physiology Bühlplatz, on Sept 1st 2nd 4th, 5th, and 6th, from 9 A.M. to noon and from 3 to 5 P.M. On Sept. 3rd there will be an excursion to St. Beatenberg

Looking Back.

FROM

THE LANCET, *SATURDAY, AUGUST 28*, 1824

PURULENT OPHTHALMIA

To the Editor of THE LANCET

SIR,—The prevalency of Purulent Ophthalmia, as mentioned in your last number of THE LANCET, calls upon every member of the Profession to use his utmost endeavours to check its ravages, and give publicity to such remedies as appear to act most beneficially upon the disease Under this idea, I beg leave to intrude upon you, that a remedy, which in an extensive practice has proved of singular utility, may be more generally known to the medical world

From the very accurate description of this disease published in the Medical and Chirurgical Transactions, by P MACGREGOR, in the year 1811, it would be superfluous to enumerate the symptoms, which must be so generally known With respect to the treatment in the first or inflammatory stage, those remedies which act generally on the constitution, I have invariably found highly beneficial, and for this purpose have employed a solution of Antim Tart. given in small doses every five or ten minutes, until nausea is produced, this, with leeches to the eye, a strict antiphlogistic regimen, and a mild fomentation or collyrium, are often sufficient to stop its progress, and frequently eradicate the disease More generally, however, an indolent inflammatory state remains, for which various astringent medicines have been employed, such as a solution of Argent. Nitr Cupri Sulph, and various others, both of the mineral and vegetable kingdoms, all of which I have extensively tried, and some with advantage But the remedy I have found of most essential service, is the Liq Plumb Subacet. in a concentrated form, and the best method for its use is by exposing the under surface of the palpebræ, whilst an assistant, with a camel's hair pencil, gently applies it to the part This is repeated every morning, and in a few days an evident improvement will be manifest From the number of cases in which I have tried it, I can speak positively as to its effect, which has proved beyond comparison superior to those in general use, and, I doubt not, should it be applied by more of the Profession, the trial will exceed their expectation

Yours, &c.

London, Aug 16 1824 T G

OPENING OF THE MEDICAL SCHOOLS

WINTER SESSION 1902–1903

LONDON

St Bartholomew's Hospital —The session will begin on Wednesday, Oct. 1st. The old students' dinner will be held in the evening in the Great Hall of the hospital, when Dr Norman Moore will preside

Charing-cross Hospital —The session will be opened on Wednesday, Oct. 1st, by the delivery of the Fourth Biennial Huxley Lecture on Recent Advances in Science and their Bearing on Medicine and Surgery, in the Anatomical Theatre of the Medical School at 4 P M, by Professor W H. Welch, M D, of the Johns Hopkins University, Baltimore. The old students' dinner will be held at the Hotel Cecil the following evening, Dr C Pye Oliver in the chair

St George's Hospital —The session will commence on Wednesday, Oct. 1st, with an introductory address, at 4 P M, by Dr T T Whipham The annual dinner will be held the same evening at the Hôtel Métropole, when Sir W H Bennett, K C V O, will preside.

Guy's Hospital —The session will begin on Wednesday, Oct. 1st, when the Lord Mayor of London will distribute the prizes A house dinner will be held in the Students' Club the same evening under the presidency of Dr Pye Smith.

King's College Hospital —The session will open on Wednesday, Oct. 1st, and the old students' dinner will be held the same evening at the Hotel Cecil, Dr T C Hayes in the chair

London Hospital —The session will begin on Wednesday, Oct. 1st. The old students' dinner will be held in the college library at 6 30 P M, Mr E Hurry Fenwick in the chair

St Mary's Hospital —The session will commence on Friday, Oct 3rd, with an address and distribution of awards by Sir A. W Rücker, D Sc, F R.S, Principal of the University of London. The annual dinner of past and present students will be held the same evening at the Whitehall Rooms, Hôtel Métropole, when the chair will be taken by Mr Edmund Owen

Middlesex Hospital —The session will open on Wednesday, Oct 1st at 3 P M Mr Stephen Paget will give an introductory address, after which the prizes gained during the previous year will be distributed by the Right Hon the Lord Sandhurst, G C S I, G C I E The annual dinner of the past and present students and their friends will take place at the Trocadéro the same evening at 7 o'clock precisely, with Dr William Cayley in the chair

St Thomas's Hospital —The session will begin on Wednesday, Oct 1st. The annual dinner in which all former and present students are invited to join, will take place at the Hotel Cecil on the same day at 6 30 for 7 o'clock, with Mr G C Franklin in the chair

University College —The session will be opened on Wednesday, Oct 1st, at 4 P M, when the Dean's report on the progress of the Medical School will be read, after which an introductory lecture will be delivered by Mr Percy Flemming, B S, F R.C S, assistant ophthalmic surgeon to the hospital

Westminster Hospital —The winter session will begin on Wednesday, Oct. 1st. The annual dinner will take place on Friday, Oct. 3rd, at the Trocadéro, Dr T Colcott Fox in the chair The secretaries of the dinner are Mr William Turner and Mr Arthur Evans, 53, Queen Anne street, W

London (Royal Free Hospital) School of Medicine for Women —The introductory address will be given by Mr Charles Burt, J P, at the Medical School on Wednesday, Oct 1st, at 4 P M

London School of Tropical Medicine—The session will begin on Wednesday, Oct 1st

PROVINCIAL.

University of Birmingham —The session will begin on Wednesday, Oct 1st.

Yorkshire College, Leeds —The session will begin on Wednesday, Oct 1st, when Mr A W Mayo Robson will deliver an introductory address

University College, Bristol —The session will begin on Wednesday, Oct 1st.

University College, Cardiff —The session will begin on Tuesday, Oct. 7th The opening address to students will be given by Dr D Berry Hart on Friday, Oct 10th

University College, Liverpool —The session will begin on Wednesday, Oct 1st.

Owens College, Manchester —The session will begin on Wednesday, Oct. 1st, when an introductory address will be given by Sir Dyce Duckworth

University of Durham —The session will begin on Wednesday, Oct 1st

University College, Sheffield —The session will begin on Tuesday, Sept. 30th, when Sir H G Howse, P R.C S, will deliver the introductory address

SCOTLAND

University of Aberdeen.—The session will open on Tuesday, Oct. 14th.

University of St Andrews (United Colleges of St Andrews and University College, Dundee) —The session will open on Thursday, Oct. 16th.

University of Edinburgh —The session will commence on Tuesday, Oct. 14th.

University of Glasgow —The session will open on Thursday, Oct. 16th

Anderson's College, Glasgow —The session will begin on Thursday, Oct 16th.

St Mungo's College, Glasgow —The session will begin on Thursday, Oct. 16th.

Queen Margaret College, Glasgow —The session will begin on Thursday, Oct. 16th

IRELAND

Queen's College, Belfast —The session will begin on Tuesday, Oct. 14th

Queen's College, Cork —The session will begin on Thursday, Oct. 16th The lectures will commence on Monday, Oct 20th

University of Dublin.—The session will begin on Wednesday, Oct 1st

Medical News

PLAGUE DUTY IN THE PUNJAB —The following is the list of medical men selected by the Secretary of State for India for plague duty during the ensuing nine months in the Punjab Dr Daniel V M. Adams Dr Joseph Ashton Dr Joseph M. Benson Mr Barnabas M Bond, Mr William Burns Mr Charles Cavanagh Mr Arthur O. De Renzi, Dr Frank L. Dickson Mr Thomas E. Dobbs, Dr Archibald Douglas Dr John S O Elkington Dr Alex Macbeth Elliot, Mr Alfred P B Ellis, Dr Robert W Fisher Dr Chas E. P Forsyth Dr Henry Fraser Dr Joseph N Gardiner Dr Frederick Goldsmith, Dr Robert W Gray Mr Charles M. Heanley Mr David Heron Dr Edward A. Houseman Dr Charles E. Husband, Mr Alexander S McSorley Mr Thomas F G Mayer Mr Ralph Mitchell, Dr John W Miller Dr John F Northcott, Mr Francis J Pearson Dr. James H. Rankin, Mr Lewis St John Reilly Dr Frank Robinson, Mr Walter Somerville Dr George Taylor Mr Edward N Thornton Dr Thomas Warner and Mr Percy J Wilkinson.

LITERARY INTELLIGENCE.—Miss Agnes M Clerke's "History of Astronomy in the Nineteenth Century" which was first published in 1885, has reached a fourth edition and has just been published by Messrs Adam and Charles Black. Owing to the alterations consequent on the superannuation of doctrines and theories which only a few years ago were implicitly believed in the work has been entirely reset. It is truer of no science than that of astronomy that the old order changeth."— The Book of Jubilees, edited with Introduction, Notes, and Index by the Rev R. H. Charles, Professor of Biblical Greek, Trinity College, Dublin, will be published by Messrs Adam and Charles Black on Sept 2nd. The Book of Jubilees is the oldest commentary in the world on Genesis and the early chapters of Exodus It was written in Hebrew in the latter half of the second century B C and therefore forms an independent witness to the form of the Hebrew text of the Pentateuch at that date From Hebrew it was translated into Greek, and from Greek into Ethiopic and Latin The entire Ethiopic version has come down to us but only fragments of the original and the other versions have been preserved. The book is full of interest both to Christian and Jewish scholars It was used by some of the writers of the New Testament, and it possesses older forms of the halacha than are found in the Mishna and older forms of haggada than appeared in the Talmud

SOME NOVEL PATENTS —A coffin has been patented having covers hinged to the opposite side walls of the body portion at their outer edges and adapted to meet at their inner edges along a longitudinal line of the casket, and outer and inner handles pivoted on one cover to turn in unison." Glass tombstones have been patented by another inventor, who has devised a method of manufacturing a block of glass having an inclosed imprint or design consisting in casting a mass of glass upon the face of a plate of glass bearing the design or imprint then casting a second mass of glass upon the back of the same. A sinew-extractor has been patented comprising two holders having channels adapted to receive one leg of a fowl and provisions for imparting a movement of one of said holders relatively to the other in a path at an obtuse angle to the channels. The specifications of these contrivances, with diagrams, will be found in the *Official Gazette* of the United States Patent Office published on August 12th, 1902.

THE PUBLIC HEALTH AND THE PLUMBER —At the Congress of the Royal Institute of Public Health held at Exeter on August 25th under the Presidency of the Earl of Iddesleigh, the following resolution was carried unanimously —

> That this 1972 Congress of the Royal Institute of Public Health held at Exeter approves of the efforts made by the Worshipful Company of Plumbers in promoting the Plumbers Registration Bill, believing that such a measure will be for the safeguarding of the public health and beneficial to all classes of the community and appeals to the Government to give facilities and support to the measure

PROMISES OF SANITARY REFORM AT MARSEILLES —Apart from the political issues involved the municipal elections at Marseilles are of international interest from the sanitary point of view Marseilles has often been described as the door to the East, and it is a door by which cholera and other epidemic diseases have too often gained admission and spread to north western Europe. Whatever may be the claims to popularity which have enabled a socialist municipality to retain office for 10 years the much needed measures of sanitation, begun by the previous municipality, have not been pushed forward in a satisfactory manner At the recent municipal elections a combination of Radicals and Republicans have obtained a large majority over the Socialists and a new municipality is now in power M Chanot succeeds Dr Flaissières as mayor and a programme of some important sanitary reforms has already been made The first item on this programme is the re-organisation of the sanitary services and with ships constantly arriving in the port that have cases of plague on board this is a matter interesting not only the town of Marseilles but a large part of Europe. Further it is proposed to erect at Marseilles a school of colonial sanitation where patients suffering from the diseases contracted in the colonies may be observed by the students At present there exists only one institution of this sort in France and this is at Bordeaux. Perhaps the proposal to build a hospital for infectious cases, which has been adopted long ago and never carried out, will be taken in hand Then there is still an enormous amount of work to be done in regard to domestic hygiene Many houses remain that have no closets and the soil is still thrown out into the street or stored in small tubs that create a great nuisance An administration, whatever its political colour that would give its earnest attention to these practical questions would earn the gratitude not only of the inhabitants of Marseilles but of all France and also of neighbouring nations who receive travellers and merchandise disembarked at this port

THE GAMBIA MEDICAL EXPEDITION —Dr J E Dutton and Dr J Todd are proceeding to Gambia upon the eighth expedition of the Liverpool School of Tropical Medicine. Their plan is to pay a six months visit to Bathurst, the Gambia territory and French Senegal and to carry on research work the French authorities having placed quarters at their disposal.

Births, Marriages, and Deaths.

BIRTHS.

JONES —On St. Bartholomew's Day the wife of H Lloyd Jones, M.D Camb. Corpus Buildings Cambridge, of a daughter

MARRIAGES.

WARD—FINCH —On August 14th, at the Cathedral Cape Town, by the Rev Arthur Brooke Arthur Blackwood Ward B.A., M B. B C. Cantab M R.C.S Eng., L.R.C.P Lond. of Northumberland Lodge Bloemfontein Orange River Colony to Angela Susan Dorothea, second daughter of the late Henry C Finch J P, of Redheath, Watford in the county of Herts Esquire, and of Mrs Charles Maynard Hallewell of Vale House, Monkton Combe Bath

DEATHS

HAYWARD —On August 6th, at 180, Elizabeth-street Hightown Manchester William Henry Hayward Surgeon aged 63 years

N.B —A fee of 5s is charged for the insertion of Notices of Births Marriages and Deaths

---

Unqualified —The university of which B is a graduate is recognised by the official publication of the University of the State of New York entitled "Medical Education as affording a genuine and thorough medical curriculum This official publication is very generally relied on by us in discriminating between genuine and bogus institutions in the United States Although the university in question is not included in the list of those published in the Medical Register as granting a registrable foreign degree the same is the case with a number of universities of high standing in Europe The place where A and B are practising is the capital of an absolutely independent State and we therefore think that our correspondent can perfectly well recognise B. Also it seems to us that the General Medical Council can have no possible jurisdiction over A, whose duty it is to comply with the registration formalities if any there be prevailing in the foreign country in question.

[illegible] —Our correspondent is advised to apply to the London Hospital Whitechapel road, London, E where there is a special department for the treatment about which he writes

O A —Will our correspondent kindly forward us his name and address?

ERRATUM —In our issue of Aug 23rd p. 600 there appeared a review of a book by Dr James Wallace He was erroneously described as M.D Glasgow " This should have read *M D Aberd*.

OUR CURRENT NUMBER

Being almost exclusively devoted to information especially interesting to Students we are necessarily compelled to defer the publication of communications on other important subjects

We tender our best thanks to those gentlemen who have at considerable personal trouble kindly supplied us with the returns and prospectuses upon which the information given in this Students' Number of THE LANCET *relative to the various medical examining bodies, hospitals and medical schools of the United Kingdom is based We regret that in some cases, however, owing to proofs having been either not returned at all or too late, certain inaccuracies may be found*

An Address

Delivered to the Graduates on July 26th, 1902 at the University of Edinburgh on the occasion of the Admission to Degrees in Medicine, and of the Conferring of the Honorary Degree of LL.D upon the Representatives of the Colonies

BY E A. SCHAFER, LL.D, F.R.S[1]

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY

LADIES and Gentlemen, Newly made Graduates,—This is a momentous day in the life of everyone of you. You have come to the parting of the ways. You are going out into the world many of you far afield. You possess youth, with its self-confidence, and you will doubtless be saying with Pistol The world's mine oyster!" But the world let me remind you, is an oyster which shuts itself up very tight, and it is not everyone who succeeds in opening it. You must be prepared for disappointments but resolved never to be disheartened by them. How few meet with uninterrupted success and such as do—are they always the better for it?

> Sweet are the uses of adversity
> Which like the toad, ugly and venomous,
> Wears yet a precious jewel in his head

You are leaving your studies behind, but, in one sense, the most important are yet in front of you. It is, I think, Lowell who has somewhere said that the most valuable part of our learning is that which we teach ourselves. And this is pre-eminently the case with medical learning You will find that it is experience, and the knowlege which can only be gained by experience, which will enable you to approach the sick bed with confidence. And while you employ your store of accumulated experience to assist you in the diagnosis and treatment of every new case which comes before you, you will by rightly using your trained powers of observation, be able to cull from each case something worth adding to that store.

This being in the main a medical graduation it is appropriate for me to address more especially those of you who have decided to pursue a medical career and as I myself happen to be outside the actual profession—although my subject, the Institutes of Medicine, belongs in a very real sense to it—I am able to view medical practice from a relatively impartial standpoint, and may therefore venture in the first place to offer some reflections upon the advantages which the profession of medicine offers to those who, like yourselves, take it up as the occupation of their lives. These advantages are, I believe, considerable, and to use a phrase which has lately become current, are not only material, but also moral and intellectual. The most obvious benefit of a material character is connected with the fact that the practice of medicine is to be for most, if not for all of you, your source of livelihood. The education which you have received in preparation for practice has been a long and expensive one, but it has a good, and probably an increasing market value. What its relative value as compared with that for one of the other learned professions may be it is not easy accurately to estimate but one thing is certain—that it is in the power of any one of you to secure at once an income which, if not large, is at least sufficient for any immediate wants you are likely to have Thanks to the abolition of the unqualified assistant good positions as assistant are at a premium, and as an introduction to family practice there is no better opening than the opportunities which such a position frequently affords. As an alternative you have the choice of many residential positions in provincial and other hospitals most of which offer unrivalled facilities for the acquirement of experience. But unless under the pressure of necessity I would not advise either of these as the best method of spending the first year or so after graduation. I would most strongly urge those who are in the position to afford the time and money to continue their clinical and pathological studies in other places or even in other countries. Nothing is better calculated to enlarge your mental vision than making the acquaintance of men and methods other than those to which you have been accustomed, nothing will develop your critical powers to the same extent. And your facility in diagnosis, which must always be the first qualification of the physician, will largely depend upon the development of those powers. But the material benefit which is represented by a fair and let us hope, a steadily increasing income, is by no means the only advantage to be gained by your having joined the ranks of the medical profession there are moral and intellectual benefits, which if less tangible are no less valuable. For it seems certain that the calling or profession to which one belongs may react upon the individual pursuing it, and may be capable of modifying his character for better or worse. It would not be difficult to illustrate this by examples drawn from any of the learned professions, but my present purpose will be served if I can point out the effect which the practice of medicine tends to produce not only on the character of the individual practitioner but also on the profession as a whole leaving the more general investigation to future philosophers, who will without doubt find it a very fertile subject of study

It will, I think, be denied by no one that the tendency of the doctor's occupation is to cultivate a sympathetic attitude towards his fellow man No matter what the sphere of his labours—whether he be the court physician making a princely income and accustomed to move in the highest circles of society, or the poorest general practitioner earning with unremitting labour little more than a living wage—we find the same qualities tending to accentuate themselves—the same disregard of self the same devotion to the interests of his patients. This is the character which has been so sympathetically depicted by a master hand in the old doctor of Drumtochty and I venture to assert that the type is to be met with, under different guises, in every town and village throughout the length and breadth of the land. In what other profession do we find so much gratuitous benevolence? Look at the amount of invaluable time which is placed at the service of the suffering poor in our hospitals and dispensaries, the numberless visits which are paid to private patients whose circumstances are such that the doctor either refuses to accept a fee at all, or makes a demand of a merely nominal nature, nay more, in many instances is ready to put his hand into his own pocket to relieve the necessities which the accident of his occupation has revealed to him. How many the instances of doing good by stealth unnoted by any pen of man but let us trust not forgotten by the Recording Angel.

See, further how this spirit of altruism, which has existed amongst physicians from time immemorial has spread from the individual to the mass and has infected the profession as a whole. In what other branches of applied science are inventions and discoveries made over as free gifts to mankind? Consider from the commercial point of view alone the enormous value of vaccination, of antisepsis in surgery We are in the habit, and rightly of recompensing the successful leaders of our armies not only with titles but with still more tangible marks of our gratitude and appreciation. But

> A wise physician, skilled our wounds to heal,
> Is more than armies to the publick weal."

Jenner it is true, obtained a grant from Parliament of £10,000, which was eventually increased to £30 000 as an acknowledgement of his services in introducing a practice which has been the means of saving thousands of lives annually and which has rendered innocuous the greatest scourge by which mankind has ever been visited but this is almost a unique instance of a pecuniary reward being conferred upon a medical man for public services. Had Jenner had Lister instead of giving freely to the world the methods which are associated with their names, patented those methods, they migh have heaped up riches beyond the dreams of avarice. But we take such gifts as a matter of course and if we ask why this is so, while workers in other branches of applied science are permitted to reap the fruit of their investigations the answer is that it is the established tradition of the medical profession to have no secret remedies and to establish no monopolies but to consider only how mankind may best be benefited. Ladies and gentlemen, it is the existence of such traditions as this which exhibits the true nobility of the profession you have chosen.

You whom I am addressing are fortunate in the time at

An Address

Delivered to the Graduates on July 26th, 1902 at the University of Edinburgh on the occasion of the Admission to Degrees in Medicine and of the Conferring of the Honorary Degree of LL.D upon the Representatives of the Colonies,

BY E A. SCHAFER, LL.D, F.R.S.[1]

PROFESSOR OF PHYSIOLOGY IN THE UNIVERSITY

LADIES and Gentlemen, Newly made Graduates,—This is a momentous day in the life of everyone of you. You have come to the parting of the ways. You are going out into the world, many of you far afield You possess youth, with its self-confidence, and you will doubtless be saying with Pistol The world's mine oyster!" But the world, let me remind you, is an oyster which shuts itself up very tight and it is not everyone who succeeds in opening it. You must be prepared for disappointments, but resolved never to be disheartened by them. How few meet with uninterrupted success, and such as do—are they always the better for it?

> Sweet are the uses of adversity
> Which like the toad, ugly and venomous,
> Wears yet a precious jewel in his head."

You are leaving your studies behind, but, in one sense, the most important are yet in front of you. It is, I think, Lowell who has somewhere said that the most valuable part of our learning is that which we teach ourselves. And this is preeminently the case with medical learning You will find that it is experience, and the knowlege which can only be gained by experience, which will enable you to approach the sick bed with confidence. And while you employ your store of accumulated experience to assist you in the diagnosis and treatment of every new case which comes before you, you will, by rightly using your trained powers of observation, be able to cull from each case something worth adding to that store.

This being in the main a medical graduation it is appropriate for me to address more especially those of you who have decided to pursue a medical career and as I myself happen to be outside the actual profession—although my subject, the Institutes of Medicine belongs in a very real sense to it—I am able to view medical practice from a relatively impartial standpoint, and may therefore venture in the first place to offer some reflections upon the advantages which the profession of medicine offers to those who, like yourselves, take it up as the occupation of their lives. These advantages are, I believe considerable, and to use a phrase which has lately become current, are not only material but also moral and intellectual. The most obvious benefit of a material character is connected with the fact that the practice of medicine is to be for most, if not for all of you, your source of livelihood. The education which you have received in preparation for practice has been a long and expensive one, but it has a good, and probably an increasing market value. What its relative value as compared with that for one of the other learned professions may be it is not easy accurately to estimate, but one thing is certain—that it is in the power of any one of you to secure at once an income which, if not large, is at least sufficient for any immediate wants you are likely to have Thanks to the abolition of the unqualified assistant good positions as assistant are at a premium, and as an introduction to family practice there is no better opening than the opportunities which such a position frequently affords. As an alternative you have the choice of many residential positions in provincial and other hospitals most of which offer unrivalled facilities for the acquirement of experience. But unless under the pressure of necessity I would not advise either of these as the best method of spending the first year or so after graduation. I would most strongly urge those who are in the position to afford the time and money to continue their clinical and pathological studies in other places or even in other countries. Nothing is better calculated to enlarge your mental vision than making the acquaintance of men and methods other than those to which you have been accustomed, nothing will develop your critical powers to the same extent. And your facility in diagnosis, which must always be the first qualification of the physician will largely depend upon the development of those powers. But the material benefit which is represented by a fair and, let us hope, a steadily increasing income, is by no means the only advantage to be gained by your having joined the ranks of the medical profession, there are moral and intellectual benefits, which if less tangible, are no less valuable. For it seems certain that the calling or profession to which one belongs may react upon the individual pursuing it, and may be capable of modifying his character for better or worse. It would not be difficult to illustrate this by examples drawn from any of the learned professions, but my present purpose will be served if I can point out the effect which the practice of medicine tends to produce not only on the character of the individual practitioner but also on the profession as a whole leaving the more general investigation to future philosophers, who will without doubt find it a very fertile subject of study

It will I think, be denied by no one that the tendency of the doctor's occupation is to cultivate a sympathetic attitude towards his fellow man No matter what the sphere of his labours—whether he be the court physician making a princely income and accustomed to move in the highest circles of society or the poorest general practitioner earning with unremitting labour little more than a living wage—we find the same qualities tending to accentuate themselves—the same disregard of self the same devotion to the interests of his patients. This is the character which has been so sympathetically depicted by a master hand in the old doctor of Drumtochty and I venture to assert that the type is to be met with, under different guises, in every town and village throughout the length and breadth of the land. In what other profession do we find so much gratuitous benevolence? Look at the amount of invaluable time which is placed at the service of the suffering poor in our hospitals and dispensaries, the numberless visits which are paid to private patients whose circumstances are such that the doctor either refuses to accept a fee at all, or makes a demand of a merely nominal nature nay more, in many instances is ready to put his hand into his own pocket to relieve the necessities which the accident of his occupation has revealed to him How many the instances of doing good by stealth unnoted by any pen of man but let us trust not forgotten by the Recording Angel.

See, further, how this spirit of altruism, which has existed amongst physicians from time immemorial, has spread from the individual to the mass and has infected the profession as a whole. In what other branches of applied science are inventions and discoveries made over as free gifts to mankind? Consider from the commercial point of view alone the enormous value of vaccination, of antisepsis in surgery We are in the habit, and rightly, of recompensing the successful leaders of our armies not only with titles but with still more tangible marks of our gratitude and appreciation. But

> A wise physician, skilled our wounds to heal,
> Is more than armies to the publick weal."

Jenner it is true obtained a grant from Parliament of £10 000 which was eventually increased to £30 000, as an acknowledgement of his services in introducing a practice which has been the means of saving thousands of lives annually and which has rendered innocuous the greatest scourge by which mankind has ever been visited; but this is almost a unique instance of a pecuniary reward being conferred upon a medical man for public services. Had Jenner had Lister instead of giving freely to the world the methods which are associated with their names, patented those methods, they might have heaped up riches beyond the dreams of avarice. But we take such gifts as a matter of course, and if we ask why this is so, while workers in other branches of applied science are permitted to reap the fruit of their investigations the answer is that it is the established tradition of the medical profession to have no secret remedies and to establish no monopolies but to consider only how mankind may best be benefited. Ladies and gentlemen it is the existence of such traditions as this which exhibits the true nobility of the profession you have chosen.

You whom I am addressing are fortunate in the time at which you are commencing practice, in the time during which you have received your training, for it is not likely that there will occur during your lifetime such a complete change in the manner of viewing nearly all problems in both medicine and surgery as we of the latter half of the nineteenth century have witnessed, nor will you be compelled to remodel all your ideas upon pathology and treatment as your predecessors of my own generation have found themselves under the necessity of doing This change has been the result of the recognition of a single principle, and the consequences of its recognition have been so momentous that I have no hesitation in affirming that the relation which it occupies to the science of medicine is of not less importance than that which the principle established by Darwin bears to biology This principle, or doctrine, if that term be preferred, which has so completely revolutionised the practice of both medicine and surgery, is, as you are aware, the doctrine of the parasitic nature of disease. Unlike the Darwinian hypothesis this one has not been sprung suddenly upon the world, but has been the slow growth of years It has, however, no less surely taken its place in medical science as an established hypothesis—nay, more than a mere hypothesis, as a well founded fact Unlike the Darwinian theory, its establishment cannot be allocated to an individual, but is the result of the independent investigations of many workers during the latter half of the last century The great French chemist, Pasteur, was a pioneer in this field of exploration, which has since yielded such remarkable results, but even before Pasteur the opinion was beginning to spread that many diseases of plants and animals, other than those which were obviously due to moulds and worms, might be caused by parasitic organisms Look, however, at the position which the doctrine now holds and see how intimately it is interwoven with the whole fabric of medicine and surgery Listerism is founded upon it, and upon Listerism is dependent the marvellous advance which surgery has made within the memory of many who are here present Consider what surgery was in the ante Listerian days You must all of you have heard, many of us know from personal experience. It was not skill that was lacking but knowledge of the nature of infective processes There have probably never been surgeons more expert than Liston and Syme, and yet, thanks to this knowledge, which has been acquired since their time, there is not one of you graduating to-day who could not with confidence approach problems in operative surgery which they with all their skill would never have dared to venture upon And if the change which has taken place in medicine is not so striking as in surgery it is none the less real The practice of protective inoculation, which was introduced some two centuries ago to mitigate the ravages of small pox, was a dim foreshadowing of what now forms the basis of the preventive and remedial treatment of a large number of affections How many diseases, the parasitic nature of which was not so much as suspected some 15 or 20 years back, are now known to belong to that class Nor is it only a question of treatment but also of diagnosis, the whole range of practice in all its aspects is affected by the establishment of this doctrine.

---

[1] The publication of this address has been unavoidably delayed owing to the pressure on our space caused by the report of the proceedings of the British Medical Association and by the publication of the Students Number

And yet we are only at the commencement of its application Every day almost sees some new fact recorded, some new discovery made, as a result of the assumption—for in many cases it must at first be only an assumption—that this or that pathological condition is produced by the growth of a parasitic organism Nor have we far to go to-day for an illustration of this statement seeing that we have just presented the Cameron Prize to Major Ronald Ross in recognition of his brilliant researches into the life-history of the parasite which produces malaria.

By the same methods as the problems of health and disease have been attacked in the past must they also be pursued in the future What are those methods? The answer is undoubted they are the methods of experiment. Although invaluable as an adjunct and for purposes of corroboration, clinical and pathological observations in man are in themselves insufficient, as a rule, for the definite establishment of any new and important principle in medicine. This is recognised by the lay press. Quite recently the *Times* newspaper, alluding to the alleged inhumanity to animals which is involved in the performance of experiments directed to the determination of questions of a physiological or pathological character, made the following remarks in a leading article "Every improvement in the healing art, from the Middle Ages downwards, has been made or perfected by the results of such experiments, which are indispensable to the progress of science and which govern the daily practice of men who never performed an experiment in their lives and possibly never saw one It would be impossible for the most ardent anti-vivisector, if he were ill, to find in any civilised country a single doctor whose treatment of his case would not be guided by the knowledge gained by past experiment, possibly by experiment performed yesterday, possibly by experiment performed 200 years ago "

It may be affirmed, without fear of contradiction, that the advance of medical science will move along the same lines in the future as in the immediate past. It is rash to prophesy, but, at any rate, one may safely commit oneself to the opinion that the problems which are at present offering themselves most prominently for solution are of a chemical nature. The chemical characters of the products which the disease parasites form within the body, the physiological action of those products, and the circumstances of their formation, the chemical characters, modes of formation, and action of the anti products which are formed by the organism for purposes of defence—these are a few of the questions which are just now awaiting solution. The sooner it is recognised that this is the direction which research must take in the immediate future the better for the progress of medical science. It must be frankly admitted that at the present moment we in this University—nay, in this country—are not in a position to satisfy the demand for research in this particular direction Nor is it a demand to be easily satisfied For the subject is one requiring a special knowledge of the principles and methods of modern chemistry as well as a thorough acquaintance with physiology This is a combination which it has hitherto been difficult to meet with, probably because most of those who take up the study of physiology and pathology have studied chemistry only in so far as it seemed necessary for the ordinary medical course and not as if chemistry were to be the subject of their life work, whereas for such investigations as these it is imperative that those who undertake them should be thoroughly trained chemists But as it is practically impossible for anyone who has not gone through the medical mill to obtain a teaching post in physiology, still less in pathology, there has been hitherto no inducement to trained chemists to direct their attention to this branch of their subject. The difficulty must be met by the establishment of special chairs of physiological and pathological chemistry to be occupied by men who are primarily chemists, but who have also some knowledge at least of physiology The necessity for this has already been recognised in some quarters In this matter, as in many others in which medical reform has been concerned, University College, London, has been the pioneer A chair of chemical pathology was established there in 1896 and an old alumnus of this University, Professor Vaughan Harley, was placed in charge. But the accommodation which the College was able to allot to the new department was sadly lacking in both extent and equipment and as the chair was without endowment it was not possible for the occupant to devote his undivided attention to his special subject. The wonder only is that with so many drawbacks so much good work has been turned out. With this partial exception there has hitherto been no chair in any university in the United Kingdom dealing exclusively or even primarily with this important branch of medical science (although the Universities of Oxford and Cambridge have made a beginning by the establishment of special lectureships in physiological chemistry) But it has been reserved for one of the newest universities—for what, indeed, may be termed a university yet unborn—University College, Liverpool—to lead the van in this movement and not only to establish but also liberally to provide for an independent chair of biological chemistry, a step which has been rendered possible by the munificence of one of the citizens of Liverpool Happy the university whose lot is cast in a wealthy city, the citizens of which are guided in the bestowal of their gifts towards objects tending to the advancement of knowledge and the alleviation of the sufferings of humanity

You will have no difficulty in perceiving that in bringing before you the example of Liverpool my object is to point out that we in Edinburgh must also be moving, we cannot allow ourselves to remain behind any university in the world in a matter pertaining to the progress of medical knowledge The need for such a chair is very evident and no one looking at the recent history of this University and considering the Carnegie benefaction, unique in its amount and object, as well as the magnificent gifts of the Hughes-Bennett Laboratory, the Usher Institute, and this very hall in which we are assembled, can entertain a doubt that when we recognise and state our wants the means of providing for them will be forthcoming Let us therefore hope that we may soon see the establishment of this chair so that the University to which we belong may maintain her place on the crest of the ever advancing wave of medical science

I have only now ladies and gentlemen, to congratulate you in the name of the Senatus upon having reached the termination of your academic career and to wish you success in your future profession. You have become members of no mean university and in taking up your membership you have also assumed the obligation to uphold all that is most worthy of the ancient reputation of your alma mater

In ordinary circumstances I should have concluded my address with these words. This is, however no ordinary function but one never to be forgotten in the annals of our University For we are assembled here not only for the customary purpose of admitting to the ordinary degrees but also that we may confer the highest distinction which it is in our power to bestow upon the chosen representatives of the British dominions beyond the seas. To you gentlemen, who have honoured us by accepting this distinction I beg to tender on behalf of my colleagues, for whom on this occasion I am privileged to speak a cordial welcome into this University Of all the universities of the United Kingdom it is the one which is, perhaps the most closely connected with our great colonies receiving on the one hand as it does, each year an important contingent of students from them and on the other hand sending out of its best to assist in establishing the new universities which are springing up within the wealthy and populous communities which, on the important occasion of the King s Coronation are so worthily represented by yourselves Although we recognise that the representation of your respective countries at that historic ceremony is the primary purpose of your visit to the mother country we do not ignore the fact that there is another object, not less dear to the heart of every Briton, whether he inhabit this or the other side of the ocean. It is common knowledge that you are also here for the purpose of endeavouring to find means to weld together more securely for mutual interest and protection the scattered parts of this vast Empire, which are already united by the more sentimental ties of blood and of loyalty to the throne Gentlemen in that endeavour we devoutly wish you Godspeed !

ON THE RESULTS WHICH HAVE BEEN OBTAINED BY ANTI TYPHOID INOCULATION

With Separate Table (see Supplement)

BY A. E. WRIGHT M.D DUB.

PROFESSOR OF PATHOLOGY ARMY MEDICAL SCHOOL, NETLEY

THE question of the utility of the process of anti typhoid inoculation has been gradually solving itself by the accumulation of statistical materials The time would now appear to be ripe for presenting this material in the aggregate, and for considering what is established by it with regard to the results of the inoculations. By the generosity of the proprietors of THE LANCET—a generosity which I desire gratefully to acknowledge—I am enabled to set out here in a synoptical form all the statistical material which I have been able to bring together in connexion with the results of anti typhoid inoculation. My cordial acknowledgments are due also to Sir William Taylor K.C B. Director General Army Medical Service for permission to make use of certain hitherto unpublished items which have been supplied to me personally

I have arranged the material at my disposal in the form of two tables. In Table I I have set out the statistical materials in the form in which those materials were originally published or rendered for consideration Into this table I have incorporated in addition to the number of the inoculated and uninoculated respectively and the number of cases and deaths in each group also certain other data, such as the period of exposure and the interval which elapsed between inoculation and the presumed exposure to infection. I have also in each case given the authority for the figures and in the case of already published statistics a reference to the literature.

In Table II I have set out such other facts as seem to me essential for the critical study of the statistics. I have had in view here on the one hand the student of statistics seeking to know how far statistical canons have in each case been conformed to and on the other hand the thoughtful man other than the professed student of statistics who may be seeking to know what conditions must be complied with before statistical evidence such as that included in Table I. becomes coercive. Let it be noted that the conditions of statistical perfection are conditions which are practically unattainable in actual life. It follows that to exact that only such statistics should be considered as are flawless would be to exact that all statistical evidence without exception should be rejected There is a way out of this dilemma. We shall, as a matter of fact, have reconciled the demands of our statistical conscience with the demands of practical life if after scrutinising and laying bare to ourselves the flaws in our statistics we in each case appraise the effect of the flaw upon the cogency of the statistical conclusion arrived at. Table II. supplying as it does examples of nearly every variety of statistical flaw will provide illustration of the importance of recognising the principle which has just been laid down. In the case of the statistics relating to the effect of anti typhoid inoculation in the garrison of India for the year 1900 (Tables I. and II. serial number 6) there is a confessed error in the enumeration of the inoculated. That error may it is estimated, amount to some hundreds " The proper way to deal with this situation is not to set aside the statistics but to consider instead what would be the maximum effect which an error of this particular magnitude is capable of exerting upon the statistical conclusion. Interpreting the error of some hundreds " in the enumeration of the inoculated in a liberal spirit as an error of 600 one way or the other the error in the enumeration of the group would amount to a 10 per cent. error This particular statistical conclusion is thus seen to be subject to a 10 per cent. error In relation to the broad issues which we propose here to discuss such an error is insignificant. It is a matter of quite subordinate interest whether the diminution of mortality in the inoculated was the 4 4-fold diminution which is actually registered or a 4 8-fold or only a 4-fold diminution.

An even more striking illustration of the importance of working in accordance with this statistical principle is afforded by the statistics relating to the garrison of Egypt for 1900 (Tables I and II. serial number 5) Here we have recorded an 18-fold diminution in the incidence of typhoid fever among the inoculated, numbering 700 odd, as compared with the uninoculated taken as some 2600 odd. If we include in the number of the inoculated those inoculated in the previous year who are specifically excluded from the statistical returns here in question we arrive at an inoculated strength of about 1000 and obtain a 25-fold diminished incidence. If again waiving the legitimacy of this course, we include among the uninoculated the full number of troops who passed through Egypt in the course of the year in connexion with military movements to South Africa we bring up our uninoculated strength to some 5000 and obtain only a 13 5-fold diminution For settling the broad issue which we have in view in this paper it matters nothing whether we accept the highest or the lowest of the above figures as representing the diminution in typhoid incidence achieved in the inoculated

Statistical flaws which make much less impression upon the imagination than those just considered may as is shown by a comparison of the conclusions arrived at in Dr A. Crombie s two statistical papers, mislead us much more seriously The conclusions arrived at in the first paper are, as is brought out (Table II 22) in connexion with the critical examination of this series of statistics invalidated by the younger age and smaller case mortality (*vide infra*) of the inoculated. In the case of Dr Crombie s second paper the first of these factors is taken into account with the result that the conclusion drawn from the comparison of the inoculated with the uninoculated falls into line with the conclusion which emerges from the aggregate of the statistics embodied in Table I

The possibility of fallacy in connexion with conclusions based on small figures is illustrated in the fact that in some of the smaller series of statistics here presented the relative case mortality of the inoculated and uninoculated differs from the relative case mortality of the two groups as deduced from the event of large comparative series of cases The possibility of a similar fallacy suggests itself also in connexion with certain of the conclusions arrived at in Dr Crombie s papers I refer (a) to the conclusion in the first paper that the protective effect of inoculation has largely disappeared after the expiration of five months

TABLE I —STATISTICS OF ANTI-TYPHOID INOCULATION

Serial number	Group which was under observation	Interval between inoculation and commencement of period of exposure	Place where group was exposed to infection	Period of observation covered by the statistics	Authority for the statistics	Reference to published literature or other source of information	Number of inoculated and uninoculated in the group		Number of cases of typhoid fever		Percentage incidence of the disease		Number of deaths from typhoid fever		Percentage death rate for typhoid fever		Case mortality—i e proportion of deaths to cases		Supplementary facts
							Inoculated	Uninoculated	In inoculated	In uninoculated	In inoculated	In uninoculated	In inoculated	In uninoculated	In inoculated	In uninoculated	In inoculated	In uninoculated

23	Officers invalided from South Africa (second series).	In most cases only a few weeks.	South Africa	No data.	Colonel A. Crombie, I M S	THE LANCET August 16th 1902.	102	85	34	28	33 3	32·9	—	—	—	—	—	—	The proportion of typhoid convalescents among the inoculated under 25 years of age was 1 in 3; among the uninoculated 2 in 3; among 13 twice inoculated 1 in 1 3; among 89 once inoculated 1 in 3 7
24	7th Hussars, South Africa.	A few week	South Africa	Dec 27th 1901, to June 20th 1902.	Captain W A Ward R A.M C	Official report.	307	244	9	20	2·9	8 2	0	3	0	1 2	0 in 9	1 in 6 7	The incidence in 73 once inoculated was 4 1 per cent; in 234 twice inoculated 2·3 per cent.

(*b*) to the conclusion that persons who undergo double inoculation are rendered more susceptible to typhoid fever than the uninoculated, and (*c*) to the conclusion that persons over 35 years undergoing the inoculation are similarly rendered more susceptible than the uninoculated.[1]

Having said this much by way of preface and illustration of the general principle which I have taken as my guide I may endeavour to indicate the general result of the statistics

GENERAL RESULT OF THE STATISTICS

It would be illegitimate to express the results in the form of an arithmetical expression representing as the case might be the average diminution of the incidence and the average diminution in the death rate from typhoid fever in the inoculated It would be illegitimate to do so because the degree of exposure to infection and the proportion of inoculated to uninoculated are in each case different.

Incidence—A study of the statistical material will, however, show that in every case except that of the City Imperial Volunteers (where the statistical materials at my disposal consist only of the bald figures incorporated in the table) and in the case of the staffs of the Portland Hospital and Imperial Yeomanry Branch Hospital at Pretoria, there was at least a two-fold reduction in cases of typhoid fever in the inoculated In certain cases, notably in those to which the statistics designated by the serial numbers 3, 4, 5, 18, and 21 apply, a greater reduction in the incidence of typhoid fever was achieved—a reduction varying from a six-fold to a 28-fold reduction

Case mortality—Superadded to the diminished incidence of the disease there is a striking diminution of case mortality, as is attested by the extensive statistical material collected by Dr R W Dodgson (Tables I. and II, 13) and more particularly by the accurate and extensive figures furnished by Major C Birt, R A M C, personally (Tables I and II. 8) and by the Staffs of the Civil Hospitals (Tables I and II., 9, 10, 11, 12, 14) in South Africa. It may be taken that in the aggregate the proportion of deaths to cases among the inoculated is approximately half that among the uninoculated.

Death-rate—The combined effect of the diminished incidence and diminished case mortality manifests itself in the diminished death rate from typhoid fever among the inoculated. The minimum reduction of death rate chronicled in the table is the twofold diminution in the case of the City Imperial Volunteers As will be seen, the reduction of death rate in case of the inoculated has often exceeded, and has seldom fallen below, a four fold reduction

CONCLUDING REMARKS.

In bringing this summary to a conclusion I am anxious to re emphasise a point already emphasised by me in previous papers[2] that there is in connexion with all protective inoculation a risk to be considered. There is the risk that (*a*) in the case where the patient's resistance is naturally low or has been reduced, as is often the case, by a previous attack of typhoid fever, (*b*) in the case where the patient is inoculated with a full dose of vaccine in actually infected surroundings, and (*c*) in the case where the patient is inoculated with an excessive dose or is re inoculated too soon, the system may be left more open to infection at a period when it stands in need of protection The facts set out in Column VI of Table II, and possibly some of those which have arrested the attention of Dr Crombie, seem to me to indicate the reality of this risk. It must be the task of the future to try to minimise the risk, on the one hand, by working out an adequate method of standardisation of the vaccine, and, on the other hand, by combining with the study of the changes produced in the blood by anti-typhoid inoculation the study of the blood in the typhoid convalescent and the study of the gradual success or failure of the process of immunisation in the actual typhoid attack. It is not necessary to insist on the urgency of this task.

---

[1] The suggestion that these conclusions may be due to the fallacy of small figures is made in the case of conclusion (*a*) in view of the fact that the Indian and Egyptian statistics which deal with an aggregate of some 4000 men inoculated in the previous year do not disclose any greater liability to attack on the part of these men than on the part of those inoculated during the current year and in the case of conclusion (*b*) in view of the fact that the larger experience of Colonel H Cayley I M S and Captain W A Ward R.A M C points (*vide* "Supplementary facts" incorporated into Table I in connexion with the eighteenth and twenty fourth series of statistics) to a greater degree of protection being conferred by double inoculation

THE

CLINICAL USE OF THE IPECACUANHA ALKALOIDS.

BY R. B WILD, M D, M.R.C P. LOND, M.Sc VICT,

LEECH PROFESSOR OF MATERIA MEDICA AND THERAPEUTICS IN THE OWENS COLLEGE, MANCHESTER.

IN a paper published in THE LANCET of Nov 23rd, 1895, p 1274, upon the Pharmacology of the Ipecacuanha Alkaloids I suggested the use of the salts of cephaëline or emetine for certain clinical purposes in place of the notoriously unreliable galenical preparations of the ipecacuanha root. Since that time the new edition of the British Pharmacopœia has been issued and the liquid preparations of ipecacuanha have been standardised to total alkaloids. Considering the differences which exist in the relative actions of the two chief alkaloids, especially as regards the emetic dose, and also the very wide divergence in the relative proportions in which these alkaloids may be present in different varieties of ipecacuanha root, it is not surprising that in spite of the standardisation to total alkaloids the galenical preparations of ipecacuanha are not altogether satisfactory Paul and Cownley have shown[1] that while two samples of ipecacuanha root may each contain about 2 per cent. of total alkaloids, in the one (Brazilian) 72 14 per cent. may be emetine and 25 87 per cent. cephaëline, and in the other (Columbian) 40 5 per cent. emetine and 56 8 per cent cephaëline, thus reversing the relative proportions of the two alkaloids. Since well crystallisable salts of these alkaloids are easily to be obtained, and at a moderate cost when the small dose is remembered, it seems desirable in the interests of accurate medication to use them in place of the less certain preparations of the root, and it is to be hoped that the next edition of the Pharmacopœia will contain a stable salt of emetine. During the last seven years I have been using certain salts of cephaëline and emetine for clinical purposes as occasion offered, both personally and in my own family, and also in hospital practice, and have every reason to be satisfied that in the hydrochloride and hydrobromide of emetine we have stable salts of reliable action which can be given in small and convenient doses for expectorant, depressant, or emetic purposes. I have had no opportunity of trying the effect of the alkaloids in dysentery or in anthrax and am not convinced that they have any special diaphoretic action The alkaloids are always best given by the mouth, as local irritation is very apt to follow hypodermic injection

For the purpose of comparison solutions of the different salts were prepared in water and in different strengths of alcohol. Half of each solution was used for clinical purposes, the other half was set aside and examined from time to time as to its keeping properties and activity Some of my solutions have now been kept for several years and are still active, it is however, not advisable to expose them to a strong light. Cephaëline hydrochloride was soon found to be less suitable for the ordinary uses of ipecacuanha in catarrhal conditions and bronchitis than the emetine salts. The emetic action of cephaëline is so powerful that it is very difficult to regulate the dose so as to obtain any effect at all without causing nausea and sickness after a few days' continued use In one case in an adult I found even $\frac{1}{100}$th grain every four hours produced nausea and vomiting within three days At the same time the effect upon the secretions of the nose and respiratory tract and the depressing action on the pulse were less marked than could be obtained by doses of emetine which caused no sickness Another reason for preferring emetine to cephaëline was that the salts of the latter appeared to be less stable, since the solutions after a time became of a brownish yellow colour when those containing emetine and kept under the same conditions were still colourless I have not been able to distinguish any difference in the mode of action or keeping properties of the two salts of emetine which I have used—viz. the hydrochloride and the hydrobromide, the solutions of these salts in 20 per cent. alcohol have remained uncoloured, clear, and active for several years, and there seems no reason to doubt their permanence within reasonable limits of time. Pharmaceutically in the specimens I have obtained the hydrobromide appeared the purer salt, as it was whiter and better crystallised. The solutions at first employed were 1 in 100 and proved too strong for convenience as the expectorant dose was from one to three minims for an adult Solutions of the strength of 1 in 1000 were then prepared (for some of these I wish to thank Dr B H. Paul who also kindly supplied me with the salts of the alkaloids) but though satisfactory in their action the dose was inconveniently large, especially for emetine purposes. The 1 in 1000 solution of emetine hydrochloride does not in my experience quite equal in activity freshly made vinum ipecacuanhæ which is standardised to 1 in 1000 of total alkaloids.

---

[1] Pharmaceutical Journal, April 26th, 1896

During the last two years I have used a solution of emetine hydrobromide in 20 per cent. alcohol containing one grain in each fluid ounce. This solution has proved very satisfactory as it has kept unchanged up to the present time is very active and reliable, and the dose is of a convenient size—viz. for adults from five to 20 minims for *expectorant and depressant purposes and from one to three* drachms as an emetic. I have also used a solution containing 1 in 100 of morphine hydrochloride and 1 in 600 of emetine hydrochloride as a sedative and diaphoretic in place of Dover's powder but have not been entirely satisfied that the action of the solution in equivalent doses is equal to that of the powder I am now comparing a solution containing 1 in 600 of emetine hydrochloride and 1 in 7½ of liquid extract of opium with another solution containing 1 in 10 liquid extract of ipecacuanha and 1 in 100 of morphine *hydrochloride. It is still too early to draw any conclusions* as to their relative value of the pure alkaloid and crude drug in either case.

My clinical opportunities of observing the therapeutical effects of emetics are so few that I have been unable to test sufficiently whether cephaëline possesses any properties (especially absence of circulatory depression) which will enable it to compete successfully with emetine and apomorphine as an emetic Unless clinical observation reveals such properties there does not seem any special indication for the use of cephaëline since even the emetic dose of the emetine salts is small enough for all practical purposes

I have nothing further to add to my former communication respecting the pharmacological action of the alkaloids save that subsequent experiments have only confirmed my former results. Ipecacuanhic acid has also been tried experimentally and save for some power of contracting blood vessels has not shown any marked pharmacological action No experiments have been done with respect to the third alkaloid present in small quantities in ipecacuanha root, but this has recently been shown to be comparatively inactive by Professor Kobert, whose work has also confirmed my chief conclusions respecting the relative actions of cephaëline and emetine.

Manchester

A PLEA FOR TENOTOMY OF THE TENDO ACHILLIS IN COMPLICATED FRACTURES OF THE LOWER EXTREMITY[1]

BY W THELWALL THOMAS F.R.C.S ENG
HONORARY ASSISTANT SURGEON LIVERPOOL ROYAL INFIRMARY;
ASSISTANT LECTURER IN SURGERY UNIVERSITY COLLEGE,
LIVERPOOL.

WE all agree that in the treatment of fractures the cardinal points aimed at are the immediate reduction of the deformity and keeping the fragments in accurate apposition during a period of some weeks. An examination of the internal structure of long bones reveals a beautiful arrangement of the bone fibres through which weight and stress are transmitted in such a manner as to distribute the force in a very much divided manner over the ends of the bones where they enter into the formation of joints The shaft itself develops into a cylindrical column, the bony tissue of which is thick and compact trace this towards the ends of the bones and it will be found to get thinner and thinner but as it does so trabeculæ of bone will be seen arising therefrom and soon interlacing with others, thus allowing the bone to expand and yet still remain as strong mechanically These trabeculæ are developed as the result of weight-bearing in the lower extremity and are best marked in bones showing prominent ridges for muscular attachments After fracture the more accurately we replace the broken fragments in the first instance the less need will there be for provisional callus. This is well shown in a transverse fracture of the tibia, where reduction is easy and subsequent deformity so slight that the actual site is not readily made out on the other hand look at the callus often found around an oblique fracture of the tibia where daily attempts have been made by hands pads and traction to maintain reduction, and we often find a large mass of callus and an altered line of the limb.

If long bones unite with any degree of deformity we have disturbed the relations of the lines of force through the trabeculæ and changed the relative relation of the joint surfaces to the weight-bearing line of the limb and not until many months have elapsed during which a re-casting of the lines of bone is taking place and a re-arrangement of the forces acting on a joint, do we arrive at a result enabling the workman to carry on his work. During all this time the patient cannot dispense with crutches or sticks and Golebiewski in his book on Diseases Caused by Accidents" pointedly remarks that if the patient has to depend on a cane for walking the rate of insurance (under the German State Insurance laws) cannot well be less than 50 per cent. I doubt whether we sufficiently realise the length of time before a slightly deformed tibia is able to bear full weight. *To a labouring man this is, of course,* very serious and ought to emphasise the necessity for striving to attain in all fractures the best possible results in the least possible time. It is our duty to reduce *accurately* deformity soon after the accident by any and every means in our power and if in any doubt we may seek the aid of x rays. Deformity is produced by the force of the accident, the action of muscles, and any subsequent rough handling To overcome the action of muscles we resort to flexion, extension and traction, and maintain the reduction by the pressure of pads, splints, and position. *Should these fail, operation* becomes necessary either tenotomy pegging, wiring or screwing The great majority of fractures of the lower extremity are readily adjusted and call for no special remark but certain fractures are always troublesome and difficult to treat—e.g (1) fracture through the lower end of the femur (2) oblique fractures of the tibia, (3) fracture of the tibia and fibula low down, and (4) fractures of the os calcis Look at museum specimens or at x ray photographs in any collection and you will see that mal union in these positions is very common, and we all know *of patients limping along many months* after the accident, wearily waiting for the time when they can dispense with assistance. An examination will quickly reveal an altered line of axis and after many months the limb may become useful, although much deformed It is this long *convalescence* that we should aim at diminishing and the secret of success lies in the accurate apposition of the fragments from the beginning Innumerable appliances have been devised to overcome the action of the gastrocnemii hamstrings and extensors of the thigh. I need only mention the double *inclined plane, Syme's stirrup* splint Macintyre's splint and Houghton's splint.

When the chief deforming agent is the gastrocnemius we must effectively prevent its action and in slight deformities this is readily *brought about by flexion. Traction often in*creases the trouble or proves irksome after a few day even if it does not damage the skin. When the muscle is acting at a great mechanical advantage the hope that it may be overcome by steady slowly increasing traction is often doomed to disappointment By traction on the leg in a very oblique fracture *of the tibia the deformity* is often increased and the attempt to remedy matters by pads often makes matters worse, for although the pointed fragment under the skin in front may be depressed the *sharp* end of the other fragment may be and often is pushed backwards into the calf muscles and the subsequent result is not satisfactory Slight degrees of flexion at the knee can be tolerated but extreme degrees cannot. If then we find that a position compatible with comfort does not relax the gastrocnemius the tendo Achillis ought to be divided. We are in danger of forgetting its usefulness in the rage for wires and screws, and it came as a surprise to me to read in Tillman's Surgery "that tenotomy of the tendo Achillis is much practised—especially in England." My observations are entirely to the contrary and I should have been inclined to replace the word "practised" by "neglected" Erichsen is almost silent on the subject, merely quoting Bryant, but he qualifies the allusion by stating that tenotomy "might be of use" in fractures of the lower end of the femur The more modern text-books mention the proceeding, but lay no stress on its application. Jonathan Hutchinson, however, in a translator's note in "Helferich's Fractures" advocates tenotomy and speaks highly of it in complicated fractures

---

[1] A paper read before the Liverpool Medical Institution on April 24th 1902.

It is a pleasure to see the difficulties of a case of oblique fracture disappear as soon as tenotomy is performed, the sharp projecting fragment immediately falls into line and the subsequent treatment becomes of the simplest description and entirely free from anxiety Tenotomy can easily be performed under eucaine, but in very nervous patients nitrous oxide, or even other anæsthetics, may be necessary I have only had occasion to tenotomise the tendo Achillis 12 times, but in each case any other treatment short of wiring or screwing would have resulted in faulty union. Even after wiring fractures of the lower extremity if any great gastrocnemius strain acts on the wire the tendon ought to be divided, otherwise the wire (or screw) will quickly loosen by bone atrophy Long before the patient is up the tendon has united and I have not found it necessary to keep oblique fractures longer in bed than transverse fractures The cases thus treated have been as follows Femur fracture of the lower end; mal-union, wiring and tenotomy Tibia upper third, comminuted. Tibia oblique, below middle—three simple and three compound. Tibia lower end, with fibula and displacement backwards—three cases Tibia old fracture, mal union, operation, lower third—one case The treatment should prove of use in separation of the lower epiphysis of the femur, fracture of the os calcis, and dislocation or fracture of the astragalus

Liverpool.

SOME OBSERVED VARIATIONS IN THE PHOSPHATES AND UREA OF URINE

BY EDWY G CLAYTON, F C S, F I C

THE appended results of determinations by the writer of phosphoric acid, urea, &c, in certain pathological and other urines, may be useful for reference. Such additional details are given as serve to indicate the character of the samples.

The unusually low phosphates and urea in the case of tuberculosis, and in sample B, as well as the evident general correspondence of the proportions of both constituents with the varying conditions represented by these specimens of urine, seem to be the points most worthy of remark Also the uric acid in the first case is decidedly low, but the salt and sulphuric acid do not present such notable departures from normal proportions

RESULTS.

[2] Zeitschrift für Hygiene Band [illegible] 1901 p. 4[illegible]

the objections to the usual posterior route do not outweigh them

Whilst operating upon a case of dilated stomach some months ago I noticed how easily the posterior wall could be reached through the gastro-colic omentum and it occurred to me that by the adoption of this route the advantages of the usual posterior operation could be obtained and at the same time the objections to it entirely avoided. The gastro-colic omentum is a thin functionless and practically bloodless membrane through which the finger can be easily pushed and is readily accessible through a small abdominal incision Moreover, when the stomach is dilated its posterior wall sags downwards below the line of its greater curvature in such a way that it can be drawn through an opening in this omentum and the whole procedure performed outside the incision When the operation by this route is complete the posterior wall of the stomach remains drawn down as a funnel shaped process and any gastric contents can be seen passing through it immediately the clamps are removed

I have adopted this gastro colic route in the following four cases and have been much pleased with it. A posterior anastomosis is obtained with a minimum of peritoneal exposure and without interfering with the transverse mesocolon The jejunum is drawn up in front of the transverse colon, as in the anterior operation, but I am not aware that this is any disadvantage It usually crosses the colon well to the left where the latter passes backwards to the splenic flexure and consequently no pressure is exercised upon it.

CASE 1. *Primary gastric dilatation, posterior gastro-jejunostomy through the gastro-colic omentum, recovery* —A man, aged 48 years, was admitted into the Bradford Union Hospital under the care of Dr Crowley on Jan. 5th, 1901 He had been a heavy drinker and gave a typical history of dilated stomach He was a big tall man but considerably wasted His weight on admission was 8 stones 1 pound The stomach was much dilated, reaching well below the umbilicus There was a well marked succussion splash No tumour could be felt. He vomited at intervals large quantities of fermenting fluid containing sarcinæ Free hydrochloric acid was present He was put upon sulphite of soda in 20 grain doses and the stomach was washed out every morning The quantities obtained from lavage were considerable, usually two or three pints in excess of the fluid poured in He could easily retain five pints of fluid in the stomach He remained under medical treatment for four months and improved for a time, although he only gained eight pounds in weight. He then began to lose ground and speedily lost weight He was therefore transferred to my wards for operation

On May 21st, 1901, I opened the abdomen and found a stomach of very large proportions without any apparent pyloric obstruction. I was about to perform the posterior operation by the ordinary route when I noticed how the posterior wall of the stomach bulged behind the gastro-colic omentum and it occurred to me that a posterior anastomosis could be very easily performed through this membrane I therefore pushed my finger through and drew out a large fold of the posterior wall I then caught up the jejunum, drew it up in front of the transverse colon, and attached it to the fold of the posterior wall of the stomach. Anastomosis was effected by a double row of sutures without any mechanical appliance. The serous suture was of silk and the mucous membrane suture of catgut The opening made was a full two inches and was situated on the posterior wall close to the greater curvature of the stomach At the conclusion of the operation I noted that the stomach wall remained drawn down at the site of the anastomosis projecting through the opening in the gastro colic omentum as a wide funnel shaped tube After the operation the patient vomited twice when recovering from the anæsthetic, after which he never vomited again He was fed by the rectum for 24 hours, after which he began with small quantities of fluid On the tenth day the sutures were removed, the wound being healed. At the end of a fortnight he was taking solid food. At the end of the third week he was up and about and from this time he was weighed weekly In five weeks he gained one stone five pounds He then went into the country for six weeks when he gained another stone I saw him some months ago He has remained quite well.

This case, the first in which I adopted this method of operating, was apparently one of primary dilatation There was no pathological change of any kind about the pylorus The size of the stomach was very great. On one occasion five pints were introduced into the stomach during lavage and 172 ounces were drawn off.

CASE 2. *Dilated stomach on which pyloroplasty had been performed five years previously, posterior gastro jejunostomy through the gastro colic omentum, recovery* —A man, aged 39 years, was admitted into the Bradford Union Hospital under my care on July 13th, 1901, suffering from symptoms of dilated stomach Five years ago he suffered from severe pain and vomiting after food. In 1896 he was a patient in a hospital in which I was resident at the time. Pyloroplasty was performed upon him for a simple pyloric stricture He says that his symptoms returned within 15 months of this operation and he went back to the hospital and was then advised to submit to gastro-jejunostomy He refused and for the past three years he had been getting steadily worse, sometimes vomiting at intervals of a few days, but usually vomiting daily On admission he weighed nine stones He was somewhat emaciated but not greatly so He stated that when in health he weighed 13 stones He suffered from most obstinate constipation, his breath was very foul, and he frequently vomited fluid which looked exactly like pure yeast. After food he had severe pain coming on within an hour of the meal and relieved by vomiting There was no definite tumour evident, but in the middle line was an old scar of a former operation He was put upon sulphite of soda and the stomach was washed out daily An excess of from one to two pints of fluid over and above the quantity introduced was usually withdrawn This treatment was tried for a month. He steadily lost flesh, his weight falling to 8 stones 4 pounds before he consented to operation.

On August 20th I opened the abdomen under ether The posterior wall of the stomach was easily drawn through the gastro colic omentum and an anastomosis with the jejunum made by simple suture, as in the first case The pylorus was surrounded by adhesions which fixed it to the liver It was of abnormally large calibre, two fingers slipping through it without difficulty The patient vomited a little mucus when recovering from the anæsthetic, after which he never vomited again He got up on Sept 10th He was then taking solid food and had gained six pounds in weight. At the end of six weeks he had gained one and a half stones He left the hospital on Oct. 17th in good health and weighing 10 stones 2 pounds [1]

This case was particularly interesting from the fact that a pyloroplasty had been performed four years previously, and the condition found at the second operation demonstrated very well how pyloroplasty may fail to relieve Whilst the pylorus may be, as in this case, permanently enlarged, the operation produces adhesions which may cripple the stomach as effectually as the stricture for which the pyloroplasty was undertaken

CASE 3. *Pyloric tumour with gastric dilatation, posterior gastro jejunostomy through the gastro colic omentum, entire disappearance of the tumour in four weeks, recovery* —A married woman, aged 26 years, was admitted into the Bradford Royal Infirmary under my care on Dec. 9th, 1901. She stated that she had been quite well up to three months prior to admission, when she noticed a lump in the right side of the abdomen, just below the margin of the ribs At the same time she began to have pain coming on in paroxysms after food She gave up taking solid food and had less pain for a time During the past six weeks she had constantly vomited after meals and the pain had been more severe She had lost flesh rapidly There had never been any hæmatemesis On admission she weighed six stones eight pounds, being very thin and somewhat anæmic The stomach was considerably dilated and showed well marked peristalsis on palpation The shape of the organ could be clearly defined and succussion splash was constantly present At the pyloric end was a circular tumour It moved up and down with respiration and was apparently connected with the stomach. It felt to be of about the size of a "penny bun " She vomited daily, generally after food The vomit was fermenting and contained sarcinæ and free hydrochloric acid.

On Dec. 18th I opened the abdomen under ether The stomach was considerably dilated, the greater curvature reaching within an inch of the umbilicus On the anterior wall close to the pylorus was a radiating puckered scar To the right of this the wall was much thickened, the whole pylorus feeling like a solid cylinder This thickening spread on to the duodenum where its advancing edge could be felt and gave a sensation of cartilage to the touch. The glands along the lesser curvature were large The pylorus and adjacent infiltrated tissues had a semi translucent appearance as if they were œdematous The whole mass was suspended from the liver by adhesions. The posterior wall of the stomach was drawn through the gastro-colic omentum and an anastomosis with the jejunum made by simple suture as in the other cases The patient vomited a little mucus on returning to the ward, after which she was never sick again The sutures were removed on the ninth day On the twelfth day she had some fish At the end of three weeks she got up She then weighed six stones ten pounds. The tumour at this date was scarcely perceptible on palpation I last saw her on March 24th 1902. She weighed eight stones one pound and was perfectly well

---

[1] This patient was seen in August, 1902. He was in perfect healt and weighed 12 stones

My first impression in this case was that the tumour was malignant The very short history without any previous illness suggestive of ulcer and the large size of the tumour, which was apparently only three months old, certainly favoured this view Against it was the early age of the patient and the presence of free hydrochloric acid When the abdomen was opened however the appearances were much more characteristic of inflammatory rather than malignant disease. The infiltration of tissue was evidently spreading from left to right, showing no tendency to invade the stomach itself. The old scar in the stomach wall was apparently the result of an ulcer long since healed. In the pylorus itself a recent ulcer probably existed, but without actually opening it I could not absolutely prove its presence. I was unable to introduce my finger into the pylorus from the stomach cavity The rapid disappearance of the tumour was the most remarkable instance of this phenomenon which I remember to have seen, occurring as it did within a month of operation.[2]

CASE 4. *Duodenal ulcer (?) gastric dilatation posterior gastro-jejunostomy through the gastro-colic omentum recovery*—A man, aged 43 years, was admitted into the Bradford Royal Infirmary under the care of Dr Campbell on Sept. 24th, 1901. He gave a history of "stomach trouble" of four years standing He said that he had "more or less constant" epigastric pain varying in severity Pain came on about one and a half hours after food and was for a time very severe. It gradually abated but was renewed at the next meal. He only vomited occasionally and the material ejected was not very large in quantity There had never been any hæmatemesis. He had lost three stones in weight in the past three years. On admission his condition was as follows. He was very thin and his expression was pinched and careworn. The tongue was very dirty and the breath was offensive. There was no abdominal tumour but the stomach was dilated, showing peristalsis on palpation There was a well marked succussion splash. The stomach held four pints easily The contents obtained by the stomach tube were fermenting Free hydrochloric acid was present. There was some rigidity and resistance of the abdominal wall over the pyloric region. Six weeks medical treatment combined with lavage produced only slight improvement and on Nov 11th Dr Campbell transferred him to my care and three days later I opened the abdomen under ether

The stomach was reached through the usual incision. It was considerably dilated but there was no pyloric tumour Beyond the pylorus, however there were some dense adhesions round the duodenum very suggestive of the presence of duodenal ulcer As the patient was very feeble I refrained from further exploration and at once performed a posterior gastro-jejunostomy in the same manner as in the preceding cases. He recovered rather slowly from the operation. There was no vomiting after the first two hours His pulse, however remained small and rapid for a day or two and he seemed to lack the power of recuperation After the first week he improved and a fortnight later got out of bed. He then weighed eight stones seven pounds. Before leaving hospital a fortnight later he weighed nine stones five pounds He was very well and had lost his grey ashy complexion and dirty tongue

In this case I omitted to excise the redundant gastric mucous membrane when making the anastomosis and the sequel shows the importance of this step. About a month after he left the hospital he complained of vomiting occasionally after meals and I readmitted him so as to have him under observation. The following facts disclosed themselves. He was perfectly well for a time and was quite conscious of food passing through the artificial opening Then, without any apparent reason he found that the stomach did not empty itself after a meal This usually occurred after an ordinary breakfast. He then had a good deal of pain and ultimately vomited when he was at once relieved. During an attack there was a well marked succussion splash. Sometimes he would go a week without one of these attacks, or on the other hand, he might have them two days running In the intervals washing out the stomach showed it to be empty the fluid returning quite clear and not increased in quantity. He had attacks much more frequently when he took only liquid diet. He was distinctly better on solid food and when he did not drink at meals On two occasions the vomited matter contained some blood These observations show clearly I think that there was some occasional accidental blocking of the artificial opening and I think there can be little doubt that this was due to a fold of mucous membrane. Since his second stay in the hospital these attacks have become less and less frequent and are apparently ceasing altogether He is putting on weight and looks very well.

In conclusion I would urge a trial of this method of performing the posterior operation. It is an easy and rapid method and combines the advantages of both the anterior and posterior routes. It certainly provides most efficient drainage of the stomach even when the patient is lying on his back. On two occasions I have noted fluid passing from the stomach into the intestine immediately the clamps have been removed. I am not aware that this route has been previously used by other surgeons, but in any case I would urge a trial of it as I feel confident that it possesses great advantages. On the other hand so far as my limited experience of it goes I have found no objection to the method.

Bradford

NOTE ON THE DIAGNOSTIC AND PROGNOSTIC VALUE OF THE LEUCOCYTE VARIATIONS IN ASIATIC CHOLERA.

BY LEONARD ROGERS M.D M R.C P LOND
F R.C.S. ENG
CAPTAIN I.M.S ; OFFICIATING PROFESSOR OF PATHOLOGY MEDICAL
COLLEGE CALCUTTA

DURING the last six months I have made some examinations of the blood in cases of cholera in order to determine if any guidance in prognosis and treatment could be derived from the conditions met with more especially as regards the use of transfusion Although the cases so far examined are much too few in number to allow of any final conclusions being drawn on this large question, yet in the course of the inquiry certain variations in the leucocytes have occurred so constantly as to appear to have a diagnostic value of their own which may be worth drawing attention to.

In Table I blood estimations in 23 cases of cholera are given and in Table II will be found six cases of non-choleraic diarrhœa of various kinds and of such severity that the patients were admitted into the cholera observation ward as suspected cases of true cholera These last all subsequently proved not to be cases of cholera, but they so closely resembled the specific disease clinically as to be just the class which is most difficult to diagnose from cholera in practice and hence they serve as good controls for purposes of comparing the blood change In 15 of the cholera cases stools were submitted to a bacteriological examination and in 10 of them pure cultures of comma bacilli were obtained. In the others similar bacilli were seen under the microscope but pure cultures were not obtained owing to their being mixed with so many other varieties, the stools being fæcal in character in these cases, having been taken in a late stage of the disease. When a typical rice-water stool was obtained there was usually no difficulty in isolating comma bacilli The cultural characters of those isolated varied greatly as in Cunningham's well known observations in Calcutta, but on preparing a serum by subcutaneous inoculation of one of them into a rabbit everyone of the other varieties clumped typically with it, although a comma bacillus obtained from water failed to do so This points to all the different varieties being specific cholera organisms, an interesting point which forms part of my larger inquiry and cannot be further dealt with here In the first two cases of Table II no comma bacilli could be isolated but material for examination was not received from the other cases.

---

[2] This patient was seen in June 1902. There was then a large malignant mass in the abdomen with all the accompanying signs of carcinoma. There was absence of free hydrochloric acid

The red corpuscles and hæmoglobin.—All the patients in Table I. were Hindus or Mahomedans except the patient in Case 15 who was a Chinaman. In the first line of the table the normal figures for healthy natives of India belonging to the poorer and ill fed classes are given, the hæmoglobin in particular being much lower than the European standard, as I pointed out several years ago, being only on the average 70 per cent. of Gowers's standard. On the other hand, the number of red corpuscles is about 5,000,000, so that the hæmoglobin value is only 0 7 In such a severe form of diarrhœa as occurs in cholera the number of the red corpuscles and the percentage of hæmoglobin both rise with the concentration of the blood and should serve as a guide to the amount of fluid lost The estimation of the specific gravity of the blood would be a more rapid way of arriving at the same result, but it was only carried out in a few cases In two of the cases the number of red corpuscles rose to over 8,000,000 per cubic millimetre and both patients died, but one patient out of three cases in which they reached between 7,000,000 and 8,000,000 recovered, as did one of the patients (Case 1) in Table II. On the other hand, four patients out of five cases in which they numbered 5,000,000 and under also died, while of 11 cases in which they were between 5,000,000 and 7,000,000 seven patients recovered and only five died. There does not, therefore, appear to be any constant relationship between the degree of concentration of the blood as indicated by the number of the red corpuscles and the death rate The hæmoglobin varied closely with the red corpuscles, the hæmoglobin value being about normal in the majority of the cases, although somewhat high in a few of them. In only one was it below normal—namely, in Case 16—and this patient had hæmorrhagic stools

Leucocytosis —It has long been known that leucocytosis is a well-marked condition in Asiatic cholera, while it is said to be most marked in the severest and most fatal cases These statements are borne out by my observations, leucocytosis having been present in every case which was examined in the earlier stages—that is, within the first two days of the disease. In nine cases it was present in comparatively slight degree, less than 20,000 leucocytes per cubic millimetre, and five of these patients recovered.[1] On the other hand, out of 14 cases in which this number was exceeded 11 patients died and only three recovered, these three however, including two out of the three cases in which over 40,000 leucocytes were found per cubic millimetre. A high degree of leucocytosis is, then, a bad prognostic sign and a slight degree a good one, yet a very high degree is not incompatible with recovery The constancy of the occurrence of leucocytosis in cholera is of importance in distinguishing it from some forms of acute diarrhœa in which it is absent, as in most of the cases in Table II It is not, however, of absolute value, as leucocytosis occurs in ptomaine poisoning and sometimes in cases of acute dysentery beginning with severe diarrhœa, Cases 3 and 1 in Table II being cases in point, and it is just these which for a time present the greatest difficulty in diagnosis

The differential leucocyte count in cholera —While working recently at the blood changes in plague I found in some of them a peculiar form of leucocytosis characterised by an unusually large proportion of lymphocytes in proportion to the degree of total increase of the white corpuscles Thus, with a total count of from 20,000 to 60,000 white corpuscles, instead of finding from 80 to 90 per cent of polynuclear cells and only about 10 per cent. of lymphocytes, the polynuclear cells showed little or no increase above the normal percentage, but the lymphocytes formed from 20 to 30 per cent. of the whole, a condition which I have not met with in the leucocytosis of inflammatory conditions or in such diseases as pneumonia or cerebro spinal fever Unfortunately, neither a marked increase in the total leucocyte count nor this peculiar proportion of the different kinds occurs at all constantly in plague, so that I have not found these changes of much practical value in differentiating plague from other diseases, as a negative result is of no value in excluding plague, although I think the finding of the condition mentioned may be of value in confirming such a diagnosis These observations led me to make similar differential counts in cholera cases, 500 corpuscles always being counted, with the result that much more constant changes of a different nature were met with, which I have found to have great diagnostic value in the limited series of cases which have so far been examined. In cholera the percentage of polynuclear cells is increased to somewhere about 80 per cent., but it seldom rises much above that point The lymphocytes are very markedly decreased, having been under 10 per cent. in 13 out of 17 cases examined on the first or second day of the disease On the other hand, the large mononuclear cells are not only decreased proportionally with the decrease in the lymphocytes, but are usually increased above the normal percentage as well as absolutely The result of these two coincident changes is that the large mononuclear cells usually outnumber the lymphocytes often to the extent of two to one, instead of being in the normal proportion of one to five. This peculiar change occurring in a leucocytosis I have not met with in any other disease than cholera. Moreover, the increased percentage of the large mononuclear cells becomes more marked as the disease progresses, especially in fatal cases The marked character of this change is still better seen by taking the total number of the different forms of leucocytes, as shown in columns 15 to 17 of Table I The polynuclear cells show a great increase in proportion to the degree of leucocytosis The lymphocytes show no proportional increase, being actually below the normal in many cases and only showing a comparatively slight increase in those cases which in the leucocytosis is of a very marked degree. On the contrary, the large mononuclear cells show an extraordinary increase, being not infrequently more than 10 times the normal number Case 12, in which no leucocytosis was present when examined on the fourth day, was one of convalescence from cholera in a malarial subject with marked anæmia, but even here the percentage of large mononuclear cells is very high and the total number is double the normal. The constancy of this decrease of the lymphocytes and great increase of the large mononuclear cells in this series of cholera cases is very remarkable and is in marked contrast with the cases of non-choleraic diarrhœa in Table II , for in not one of these last is either the percentage or the total number of large mononuclear cells increased above the normal limits in spite of leucocytosis being present in two of the cases

It will be advisable to mention here the nature of the cases in Table II in which all of the patients were admitted into the cholera observation ward as possibly suffering from cholera. The first two patients were sent by the port medical officer as being suspected cases of cholera and were examined by me very shortly after admission, when the subject of Case 1 in particular presented the general aspect of a patient suffering from cholera The higher number of red corpuscles and the percentage of hæmoglobin in Case 1 were equal to those met with in severe cases of cholera and a slight degree of leucocytosis was present. The differential leucocyte count, however, of both cases failed to show the increase of the large mononuclear cells, which at that time had been found in 17 consecutive cases of cholera, and I thought that I had met with exceptions to the general rule On the next day it appeared that the patients were suffering from very acute attacks of dysentery and they were removed from the cholera observation ward In Case 3 the patient was taken ill 10 hours after a meal at a Bengali hotel and was admitted soon after as a case of cholera. He had profuse diarrhœa and sickness, but all the stools were coloured brown and were never typical of cholera and he made a good recovery, the physician in charge subsequently coming to the conclusion (without knowing the result of the blood examination) that the case was one of ptomaine poisoning and not cholera. Case 4 was similar to the last, only it proved fatal, but no history could be obtained and unfortunately the stools of these last two patients were not sent for bacteriological examination It is therefore just possible that they may have been cholera cases which did not show the blood changes described in this paper, but in the absence of exact proof I can only accept

---

[1] In one of the fatal cases granular kidneys were found This is of interest in connexion with the fact that in 70 post mortem examinations on cholera cases which I analysed recently I found granular kidneys to be much more frequent than they were in the cases of those dying from other commoner diseases showing that if a patient had granular kidneys there was very little chance of his surviving an attack of cholera.

the conclusion of Captain Delany, M B , I M S , that clinically they were not cholera cases, and I may also take this opportunity of thanking that officer for kindly allowing me to examine his cases The patient in Case 5 was a woman who while suffering from malarial fever took two pills, after which she was violently purged 11 times and also suffered from vomiting She was admitted into the cholera observation ward and subsequently was transferred to the general ward, where she had malignant tertian fever with ring shaped parasites Her blood while suffering from the diarrhœa showed the typical low total leucocyte count, with high percentage of large mononuclear cells, which is characteristic of malaria, together with a high percentage of lymphocytes, illustrating well the difference between the high large mononuclear counts of cholera and malaria respectively Case 6 was another case of ptomaine poisoning following the consumption of prawn curry late at night, the patient having also been admitted into the cholera observation ward, but she subsequently proved not to be suffering from cholera. This series of cases of non choleraic diarrhœa is a very small one, but they form the whole of the cases admitted as suspicious of cholera during the same period as the true cholera cases in Table I occurred, came under observation in the Medical College Hospital, and hence are just the cases which it is most difficult to differentiate from cholera The fact that none of them show the changes met with in all the cholera cases strongly supports the diagnostic value of the peculiar leucocyte count of cholera described above, although it will be necessary to examine a much larger series of cases before the exact limitations of this new method of diagnosing cholera can be established This leucocyte test has at least the great advantage that it can be carried out within an hour or so with only the aid of a slide, a simple stain, and an ordinary high-power microscope (a one sixth inch lens), whereas the bacteriological diagnosis takes a day or two with the aid of a properly equipped laboratory, while, owing to the great variability of cholera comma bacilli, both in their power of liquefying gelatin and in the presence or absence of the indol reaction, considerable experience is required for its safe application, including, in order to be quite certain, the carrying out of the serum test.

The prognostic value of the leucocyte variations in cholera —If the leucocyte variations in cholera above described are of a specific nature then it might be expected that their degree might bear some relationship to the severity and mortality of the disease The following data are of interest in this connexion We have already seen that when the leucocytosis is of less degree, with a correspondingly low total polynuclear count, the prognosis is comparatively good In the case of the leucocytes, on the contrary, we have seen that in cholera a very low percentage and a comparatively low total count is the characteristic feature On classifying the cases according to the percentage of lymphocytes met with we find that out of 16 cases in which less than 10 per cent. were found no less than 12 ended fatally, while out of seven cases in which over 10 per cent. were present four patients recovered and only three died. On the other hand, there is no such relationship between the total number of lymphocytes per cubic millimetre and the mortality, which is what might have been expected, as the tendency of the high degree of leucocytosis in fatal cases to increase the number of lymphocytes is counteracted by the opposite tendency of the low percentage of lymphocytes in severe cases Lastly, on turning to the large mononuclear corpuscles we find that out of six cases in which under 10 per cent. were found four patients recovered and only two died, while, on the contrary, out of 15 cases in which over 10 per cent. of large mononuclear cells were present only three patients recovered and 12 died. The total number of large mononuclear cells per cubic millimetre shows a similar relationship, as in this case the favourable low degree of leucocytosis coincides with the equally favourable low percentage in reducing the total number of these corpuscles and *vice versâ* Thus we find that recovery took place in no less than four out of five cases in which the total number of large mononuclear cells was less than 2000 per cubic millimetre, while out of 18 cases in which over 2000 were present 14 patients died and only four recovered We therefore conclude that there is a definite relationship between the decrease of the percentage and the total number of large mononuclear cells and the severity of the disease—a relationship of the very peculiar leucocyte changes described which it would be difficult to explain on any other ground than that these changes are of a specific nature This fact, taken with the constancy of these changes in the consecutive series of cases examined and their absence in cases of non choleraic diarrhœa, encourage one to believe that a larger experience will confirm the conclusions derived from a study of the data recorded in the tables of this paper —namely, that the leucocyte changes described above have a considerable value as a simple and rapidly applied guide in both the diagnosis and prognosis of cholera.

Calcutta.

ENVIRONMENT AS A CAUSE OF AGUE

BY MATHEW D O'CONNELL, M D R.U I ,
COLONEL, ROYAL ARMY MEDICAL CORPS PRINCIPAL MEDICAL OFFICER, NORTH EASTERN DISTRICT

THE proceedings of the Malaria Congress recently held at Nagpur, Central India, under the presidency of Colonel A. Scott Reid, I M S , were full of interest and have led me once again to invite the attention of the profession to meteorological environment as a probable cause of those cases of malarial fever in which parasites cannot be discovered in the blood In a paper read at the congress Dr Stephens and Dr Christophers stated that cases occurred, with fever clinically identical with malarial fever, in which parasites could not be found in the blood, after repeated search, before quinine had been given It was also stated that in large numbers of cases of fever with enlarged spleens examined in Calcutta, the authors had seldom found the parasite in peripheral blood, although pigment was sometimes obtained by spleen puncture Instances of failure to find the parasite in undoubted cases of malarial fever were narrated and every speaker at the congress affirmed the malarial nature of the cases of chronic fever with enlarged spleen. It would appear from this that under the term "malarial fever," as it is understood at present, are included two clinically identical, yet etiologically distinct, fevers which for convenience may be referred to here as (1) parasitic malarial fever and (2) non parasitic malarial fever The diagnosis of cases of the first class would, of course, rest on the recognition of the parasite in the blood by experienced observers, for, as Manson says, "negative results by amateurs are valueless, and a positive result is not much more to be relied on "[1] The second class would include all fevers clinically identical with malarial fever in which parasites cannot be discovered in the blood It is to fevers of the latter class alone that I refer in this paper Such fevers are, in my opinion, obviously and indisputably due to the meteorological environment under which they arise By this environment I mean the hot, moist, stagnant atmosphere under which they become most prevalent and which was for many years considered a sufficient explanation of their cause First, as regards this environment it is obvious that it may be of a higher degree of intensity in some places than in others, in some years than in others, and in some seasons than in others, but I hope to demonstrate that the inevitable effect of exposure to such environment is to produce an intermittent excess of water in the blood This intermittent excess of water in the blood will be seen to afford a clear explanation of the intermittent pyrexia, the anæmia, the melanæmia, the enlargement of the spleen, and the other conditions characteristic of malaria.

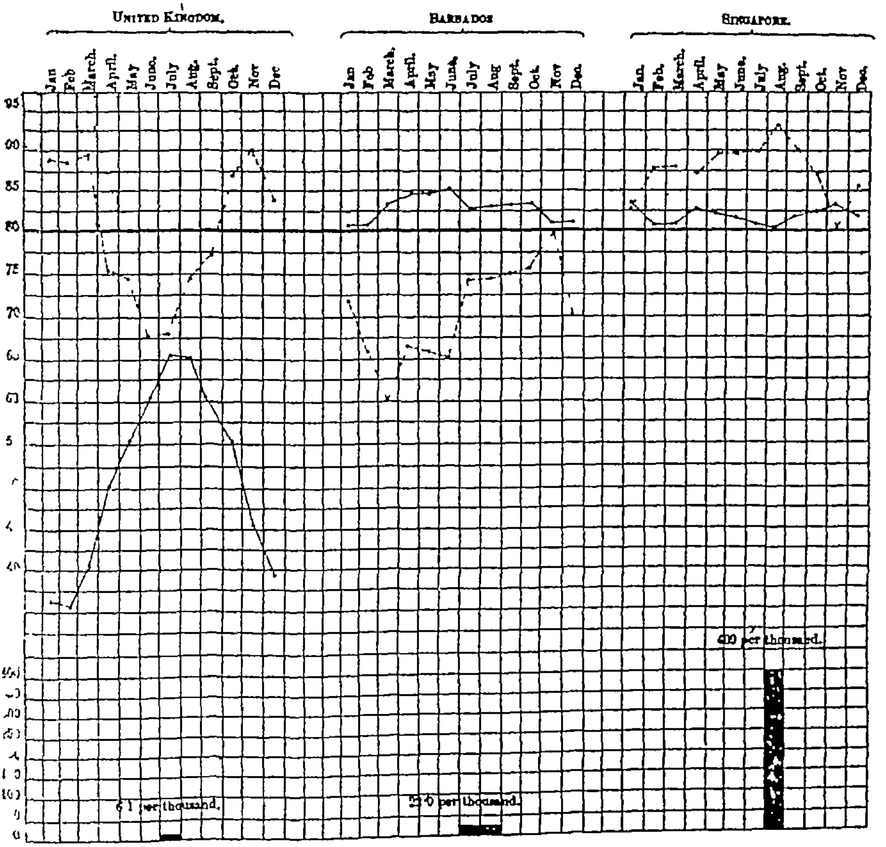
I.—THE METEOROLOGICAL ENVIRONMENT UNDER WHICH INTERMITTENT FEVERS BECOME PREVALENT

The meteorological conditions under which intermittent fevers become prevalent have long been known and are indicated in the attached chart which I have constructed from figures contained in the annual report of the Army Medical Department. It shows at a glance the difference between a malarial and a non malarial environment Where intermittent fever becomes prevalent, as at Singapore, both the atmospheric temperature and the atmospheric humidity are high, the mean atmospheric temperature being above 80° F , and the mean atmospheric humidity considerably above 80 per cent. of saturation throughout the year On the other hand, where intermittent fevers are not prevalent, as in England or at Barbados, the mean atmospheric temperature or the mean atmospheric humidity, or both, will be much lower In Barbados, although the mean atmospheric temperature is indeed higher than at Singapore, the mean atmospheric humidity *is* much lower whilst in England, although the mean atmospheric humidity is as high as at Singapore for several months in the year the mean *atmospheric temperature is very much lower* Thus *from* the chart it is apparent that the meteorological environment under which intermittent fevers become prevalent is not simply a high atmospheric temperature or high atmospheric humidity but a high atmospheric temperature *and* a high atmospheric humidity, in other words the environment under which intermittent fevers become most prevalent is the hot, moist stagnant atmosphere, as has been known for a long time. What is the effect of exposure to such meteorological environment?

---

[1] Brit Med Jour , May 17th, p 1212

CHART SHOWING THE METEOROLOGICAL ENVIRONMENT UNDER WHICH INTERMITTENT FEVERS BECOME PREVALENT



The black line shows mean atmospheric temperature. The dotted black line shows mean atmospheric humidity saturation = 100 The figures 0 to 400 show admissions per 1000 of strength for ague per annum The figures 35 to 95 show degrees Farenheit and degrees of humidity

II —Exposure to this Meteorological Environment Produces Intermittent Excess of Water in the Blood

The amount of water in healthy blood is about 790 parts in 1000 During winter and spring about 80 ounces of water are taken in daily as drink and food and the same quantity or a little more excreted daily During summer and autumn the amount taken in as drink is considerably increased and there must of course be a corresponding increase in the amount excreted otherwise the amount of water in the blood would become excessive. Excretion of water from the blood takes place from the kidneys, the lungs the skin, and the intestines Practically the amount excreted by the intestines remains constant in health but the amount excreted by the kidneys and by the skin and lungs *varies according to the atmospheric temperature* In winter and spring when the atmospheric temperature is low about two-thirds of the total quantity of water or 60 ounces are excreted by the kidneys and one-third or 20 ounces by the lungs and the skin. In summer and autumn when the atmospheric temperature is high water is excreted chiefly by the skin and the lungs and the amount excreted by the kidneys is correspondingly reduced. The evaporation of this increased quantity of water from the lungs and the skin keeps the body temperature normal under exposure to very high atmospheric temperatures But if during this season when water is being excreted chiefly through the skin and the lungs any influence impedes its free excretion through these channels without at the same time producing a compensating increase in the amount excreted through the kidneys the obvious result must be an increase of water in the blood

Now the [illegible] 60 to 95 per cent throug [illegible] as shown in the char [illegible] the free excretion of water from skin and lungs For atmospheric air can only take up as much aqueous vapour as will saturate it

Moreover, there was no fall of temperature which would be sufficient to produce a compensatory increased excretion of water through the kidneys. Hence, when ague was so prevalent at Singapore the environment was such as must certainly produce increase of water in the blood. Wherever such environment is found an intermittent fever will certainly also be found. It will be explained later why this increase of water in the blood must be of an intermittent character The environment given in the chart for Singapore may be taken as typical of the environment under which intermittent fevers reach their maximum of prevalence continued throughout the year In India and some other countries such an intense degree of this environment is usually found, with few exceptions, at only certain seasons of the year For instance, in the hot season in India the atmosphere is intensely dry, containing perhaps only 20 or 30 per cent of saturation, and evaporation of water from skin and lungs is consequently enormous To this succeeds the rainy season, almost quite suddenly, and the atmospheric humidity increases to 80 or 90 per cent of saturation I have often in India seen the dry and wet bulb thermometers register the same temperature at this season, indicating that the atmosphere is saturated with aqueous vapour and therefore completely obstructing evaporation from skin or lungs. The fall of atmospheric temperature accompanying the setting in of the rains is slight and only temporary It is not sufficient to produce increased excretion of water from the kidneys, as perhaps anyone who has resided in India will have observed Consequently water must accumulate in the blood and tissues unless the amount taken in drink be largely reduced Experience, however, teaches us that instead of being reduced the amount taken during the rainy season is just as much as during the previous hot dry season

III —THERE IS KNOWN TO BE EXCESS OF WATER IN THE BLOOD OF THOSE WHO SUFFER FROM INTERMITTENT FEVER.

Manson[2] describes malarial blood as pale lake coloured, thin, and watery Liebermeister states that there is excess of water in the blood of those who suffer from ague, and that the wasting of the body in ague is sometimes concealed by the excessive amount of water in the blood and tissues. He also says that from this cause the weight of the body may be increased as much as 10 pounds, although there may be only slight œdema of the ankles to indicate an excess of water in the blood and tissues[3] In addition the dropsical effusions which are not infrequent sequelæ of ague perhaps also indicate an increase of water in the blood of those who suffer from the disease

Let us next inquire what are the obvious effects of an increase of water in the blood produced as indicated.

IV —EXCESS OF WATER IN THE BLOOD PRODUCES PYREXIA.

The normal temperature of man is 98 4° F or 37 0° C and this is the product of two factors—(*a*) the amount of heat produced within the body and (*b*) the amount of heat given off, or lost, from the body As regards the first it is known that the source of heat production within the body is the metabolism or tissue change which takes place in every act of vital energy It has long been known that this metabolism can be increased by the free internal administration of water If experimental proof of this be asked for pathologists tell us that injection of water into the blood causes a rise of temperature[4] Hence there can be no doubt but that an increase of water in the blood produced by meteorological environment will in its turn produce an increase of metabolism or heat-production in the body But meteorological environment produces excess of water in the blood by impeding evaporation of water from the skin and lungs—that is, by diminishing heat loss If it thus causes increased production of heat within the body and diminished heat loss from the body, as above described, the result must be increase of body temperature—pyrexia. Indeed, this has been proved experimentally by Frey and Heiligenthal who found that exposure in a Russian or hot vapour bath of 113° F (45 5° C) for 25 minutes raised the body temperature to 104 3° F (40 3° C), whilst exposure in a Turkish or hot dry air bath of 149° F (64 5° C) for 50 minutes only raised the body temperature to 101 6° F (38 6° C) The explanation of this is plain. In the hot dry air bath evaporation of water from the skin is much increased and keeps the temperature down In the hot vapour bath evaporation of water from skin and lungs is much impeded by the amount of water vapour in the air and therefore the body temperature rises The temperature and humidity of the air during the fever season in tropical countries differs very little from those of the Russian vapour bath, and therefore such environment will as certainly, if not so rapidly, produce pyrexia in those exposed to it.

The weakest link in the parasitic theory of malarial fevers always seems to me to be the unsatisfactory explanation which it affords of the pyrexia, which is, after all, the chief clinical feature of these diseases Laveran himself and other eminent authorities on malaria, when referring to the pyrexia, are compelled to say that the pyrogenic agency is "most likely" or "presumably" or "probably" some toxin, which is liberated from the sporulating parasite shortly before or during the rigor, and which is a solvent of hæmoglobin. The existence of any such toxin, however, is not only apparently not proven, it is but plausible conjecture But where is the necessity for assuming the existence of a problematical toxin born of a sporulating parasite in those cases clinically identical with malaria in which parasites cannot be found, when Payne assures us that injection of water into the blood causes a rise of temperature when Liebermeister declares there is this increase of water in the blood in ague, and when, as I have shown above, this increase of water in the blood is the inevitable result of exposure to the meteorological environment found in malarial countries or climates?

V —THE PYREXIA CAUSED BY INCREASE OF WATER IN THE BLOOD DUE TO METEOROLOGICAL ENVIRONMENT MUST BE OF AN INTERMITTENT CHARACTER.

To make this evident it is only necessary to point out that the environment which produces excess of water in the blood is of intermittent intensity, for in all climates atmospheric temperature and humidity undergo a diurnal variation. The highest atmospheric temperature is usually about 4 o'clock P M daily, when, as a rule, the atmospheric humidity is at its lowest This is the period when evaporation of water from skin and lungs is free On the other hand, the lowest atmospheric temperature is reached daily about 4 or 5 o'clock A M , and then the atmospheric humidity is at its maximum. This is the time when free evaporation from the skin and lungs is most impeded In cold climates this is compensated for by the increased flow of urine produced by the fall in atmospheric temperature at night. But in the unhealthy season in tropical climates there is little or no fall in atmospheric temperature at night to produce this compensating excretion of water through the kidneys, as I daresay anyone will admit who has lived in a malarial climate during the unhealthy season. Consequently water accumulates in the blood, chiefly during the night. Now, as we have seen, the causes producing this increase of water in the blood are more active during the period from sunset to sunrise in the tropics and less active during the period from sunrise to sunset. This intermission in the activity or intensity of the cause must produce a similar intermission or tidal wave in the increase of water in the blood If the increase of water in the blood is of this intermittent character, so will the pyrexia produced thereby also be

Now in connexion with this point, that the intensity of the environment producing increase of water in the blood is greater by night than by day, may be noted the fact admitted by all, that attacks of intermittent fever most frequently commence at night or in the morning Why the intermittent fever produced in this way is quotidian in some and tertian or quartan, &c , in others would appear to depend on (*a*) the previous condition of the blood of those exposed to the environment, and (*b*) the intensity of the environment With regard to the former it is known that in different individuals the quantity of water in the blood varies within certain limits, the average quantity being 790 parts of water in 1000 of blood. It will, of course, require exposure to the environment for some time, more or less, before the quantity of water in the blood is increased to that degree which causes pyrexia. Let it be assumed that the degree which causes pyrexia is 830 parts in 1000 Then if four men whose blood contains respectively 790, 800 810, and 820 parts of water be exposed to such environment it is evident that the increase of water which causes increased metabolism pyrexia, will be most rapidly produced in the man whose blood originally contained most water—820 parts. It only requires 10 parts added This also accords with experience which teaches that those with the poorest or most watery blood most quickly contract ague when exposed to the environment. It will, of course, take longer in the other men to produce the 830 parts of water the man whose blood was in the first instance normal (790 parts) requiring the longest exposure. Again, with regard to the intensity of the environment, let it be assumed that the degree of intensity to which these four men are exposed is such that it will produce an increase of water in the blood equal to 10 parts by one night s exposure Then it is evident that the blood of the man containing originally most water—i.e 820 parts—will have its water increased to that degree which causes pyrexia, 830 parts, by *one* night s exposure to the environment , and although during the following 12 hours (day) critical elimination (sweat) may reduce it to the original 820 parts, still if exposure to such environment continues 10 parts of water will be added again the following night, reproducing the necessary 830 parts of water increased metabolism, and pyrexia—that is the paroxysms are reproduced once in every 24 hours and the type is consequently quotidian. In this way paroxysm follows paroxysm until medical treatment be adopted or as will be explained hereafter the red blood corpuscles are so much reduced that the hæmoglobin is not sufficient to provide material for the metabolism causing the pyrexia, or until the environment changes At the same rate of increase—viz. 10 parts each night—it will require two nights exposure to produce the increase to 830 parts of water in the blood of the man containing originally only 810 parts and after elimination (sweat) it will take two nights to reproduce, that is, the degree necessary to cause the increased metabolism and consequent pyrexia is only produced every second day There will be one day of apyrexia. That is the type in this case will be tertian Similarly it will require three nights exposure at an increase of 10 parts nightly to increase the water of the blood in the man, containing originally only 800 parts, to the degree, 830 parts, which I assume produces pyrexia. It will only be produced and reproduced on the fourth day—that is, the type of fever in this man will be quartan. In the blood of a man containing originally only 790 parts of water it will take still longer exposure to produce, and after elimination to reproduce, the necessary 830 parts. In those with still less water in their blood and whose eliminatory organs are perfect it is conceivable that it may not be possible by any exposure to increase the water to 830 parts, and in such cases we should expect immunity from the disease.

---

[2] Tropical Diseases p 71

[3] Hilton Fagge, p 48

[4] Payne's General Pathology, p 144

It can be seen then if ague is due to excess of water in the blood produced by environment, why the pyrexia should be intermittent in character and also why the type should be quotidian in some and tertian or quartan in others It also becomes apparent why persons with the poorest or most watery condition of blood should most certainly and rapidly contract the disease when exposed to the environment whilst those with normally less water in their blood are less liable to contract it.

Moreover if ague is due to excess of water in the blood produced by environment it becomes evident why quotidian is the most common type in tropical climates while tertian or quartan is the more common type in temperate climates For it is to be remembered that climates as regards their atmospheric temperature and humidity differ only in degree. In tropical climates in the unhealthy season of the year the environment (temperature and humidity) is of a higher degree of intensity and in temperate climates lower Hence in tropical climates the degree of hydræmia that produces pyrexia will be more quickly produced and after elimination (sweat) reproduced that i the type of ague most commonly met with in tropical climates should be that with the shortest period of apyrexia—viz. quotidian, if caused by environment. In temperate climates on the other hand, the environment not being of so intense degree must of course take longer to produce and after elimination (sweat) to reproduce the degree of hydræmia that causes pyrexia that is the type of ague most common in temperate climates if this theory is sound should be that with a longer period of apyrexia—viz. tertian or quartan. In both cases this corresponds with experience. In unusually hot summers of cold climates the environment which causes increase of water in the blood will also sometimes if seldom, be found. Hence the explanation of cases of intermittent fever in cold climates occasionally Moreover as the amount of water in the blood depends to a great extent on the balance being maintained between the amount taken in in food and drink and the amount excreted, and as the amount excreted depends to a certain extent on the functional activity of certain organs—skin, lungs kidneys &c.—it can be seen how deranged function of such organs might of itself produce increase of water in the blood altogether independently of external environment. By such functional derangement the occurrence of those anomalous cases of ague which arise in those climates, seasons or localities where the hot, moist stagnant atmosphere that produces increase of water in the blood is not found may be explained.

VI.—EXCRETION OF WATER FROM THE BLOOD REDUCES THE TEMPERATURE TO NORMAL IN AGUE.

We know that free elimination of water from the blood in ague reduces body temperature to normal Free sweating obviously does so. This fact in itself is strong presumptive evidence that the increase of water in the blood is the cause of the pyrexia. For there are many other diseases in the pyrexia of which sweating does not produce this effect. Moreover although sweating is the usual method of termination of a paroxysm of intermittent fever the same result—i.e. reduction of temperature to normal—also follows free elimination of water by the kidneys or by purging These two latter processes however only reduce the amount of water in the blood and so reduce metabolism or heat production, whilst sweating besides reducing in the same way heat production, also increases heat loss and thus more quickly reduces temperature to normal.

It is very suggestive that in the collapse stage of cholera, when elimination of water from the blood has been enormous and the blood remains thick and tarry the body temperature *is subnormal* and as *absorption is restored and water again* taken into the blood the temperature rises perhaps above normal

VII.—INCREASE OF WATER IN THE BLOOD PRODUCES *OLIGOCYTHÆMIA.*

It has long been known that when water is added to normal blood the red corpuscles lose their discoid form become spherical, swollen, and dropsical the hæmoglobin is washed out of them and ultimately they disintegrate and disappear Hence it can be seen that increase of water in the blood caused by meteorological environment which I have shown produces an intermittent pyrexia will also produce the extensive destruction of red blood corpuscles which is so characteristic of ague.

The tissue chiefly destroyed by the metabolism of pyrexia doubtless differs in different fevers, but in ague the red corpuscles of the blood are chiefly affected leading to their extensive destruction and consequent anæmia and melanæmia. Hæmolysis or destruction of red blood corpuscles is, however a process which is always going on even in health within the portal circulation. There the hæmoglobin *escapes from the old red corpuscles and is in part* converted into new red corpuscles and in part into pigment. Such pigment is taken up by the hepatic cells and forms the colouring matter of the bile urine &c If it is produced in quantity exceeding the amount that the hepatic cells are capable of converting into the colouring matter of the bile &c it is obvious that it must find its way into the general circulation and into the tissues especially of the spleen, liver kidneys &c. thus causing melanæmia. Professor Hunter who closely investigated this hæmolysis, tells us that this process may be increased by two sets of causes—viz. direct and indirect. The direct consists of agents such as water which injected into the blood act directly on the red corpuscle liberating their hæmoglobin and destroying them The indirect consists of agents which act on the red corpuscles through the medium of the splenic cells The increased hæmolysis of disease Professor Hunter adds is similar to that produced by indirect hæmolytics with two exceptions—namely malaria and hæmoglobinuria—which he attributes to the direct action of the parasites on the blood discs This may indeed be so But in those cases of ague in which no parasites can be found why attribute the increased hæmolysis to their influence instead of to the increase of water in the blood which Liebermeister assures us is present in all cases of ague which Professor Hunter asserts to be a most powerful direct hæmolytic, and which I have attempted to show in the preceding remarks is the inevitable result of exposure to the meteorological environment under which malarial fevers become most prevalent? During hæmolysis Professor Hunter describes the appearance of the following forms in the blood (1) colourless spherules albuminous and highly refractile, of various sizes, and (2) coloured spherules A red corpuscle becomes constricted at some portion, dividing into two parts, connected by a colourless portion These are best studied by warming blood to 112° F, a temperature not much above that of the blood in the portal circulation during a paroxysm of ague The corpuscle then breaks up into a number of highly coloured spherules This description of the disintegration of a red corpuscle by a temperature of 45° C forcibly reminds one of the sporulation of parasites, as described by plasmodists during each paroxysm of ague Of course, this resemblance of the disintegration of red blood corpuscles to the sporulation of parasites becomes more suggestive when it is remembered that hæmolysis is always more active within the portal circulation—the very situation where plasmodists tell us the parasites may be found when they cannot be found in peripheral blood 3 Stromata, or decolourised red corpuscles, are also described by Hunter as appearing during hæmolysis He adds that they are best studied by the injection of water into the blood

Now, if these forms—colourless spherules, coloured spherules which break up into a number of highly coloured bodies and stromata—are produced within the portal circulation in health and if, as Hunter tells us, their production is increased by heat (45° C or 112° F) and by injection of water into the blood, it is obvious that their production must be considerably increased during each paroxysm of ague when there is increase of water in the blood and the temperature of the blood within the portal circulation is nearly, if not quite, as high

Manson,[5] a high authority on malaria, tells us that the destruction of red blood corpuscles in malarial disease is greatly in excess of anything which can be accounted for by the number of corpuscles attacked and consumed by the parasites The number of parasites found in the blood might account for a destruction of 1 per cent or even 5 per cent., but not for a 20 per cent. destruction, which is not uncommon even after a single paroxysm of ague If, however, there is a form of ague, as I contend, due to excess of water in the blood this would account not only for a 20 per cent destruction of the corpuscles, but when extreme in degree it would explain the almost total destruction of blood corpuscles For increase of water in the blood will affect every corpuscle in the blood, and the greater the increase of water the greater will be the destruction of blood corpuscles and liberation of hæmoglobin Indeed, so well recognised is this that hæmatologists consider the specific gravity of the blood affords a reliable test of the number of red corpuscles and their hæmoglobin value [6]

When the liberated hæmoglobin exceeds the amount that the hepatic cells are capable of converting into biliary and other pigments then it will presumably appear in the urine This would seem to indicate that hæmoglobinuric fever owns the same origin as the non parasitic intermittent fevers which only I refer to in this paper This view gains support from the facts that hæmoglobinuric fever is found in those climates where is found at times an extreme degree of the meteorological environment that produces excess of water in the blood, that there exists some as yet unexplained connexion between this disease and malaria, and, as Manson says, the opinion that it is of parasitic origin is based more on considerations of probability than on logical deductions from demonstrated facts [7] If, as I am trying to prove there is a form of malarial fever due to excess of water in the blood caused by meteorological environment then the explanation of the connexion between malaria and hæmoglobinuric fever is not far to seek

VIII.—AN INCREASE OF WATER IN THE BLOOD PRODUCES PSEUDO-PARASITES.

It cannot be said that increase of water in the blood will produce parasites, but it will certainly produce those bodies which are called pseudo-parasites They were at one time considered to be the cause of malaria [8] Indeed, there are many still who consider that true parasites can with great difficulty be distinguished from pseudo parasites Mannaberg admitted that in a minority of cases they could not be distinguished and Manson says that it takes a large amount of practice to be able to discriminate between parasites and vacuoles in the red corpuscles in fresh films. Indeed, there are even still a few who maintain that they are indistinguishable for the simple reason that they consider the parasites to be merely products of hæmolysis such as may be found within the portal circulation in health in any climate and in the peripheral circulation of those who suffer from malarial fevers However this may be, it seems certain that increase of water in the blood will produce pseudo-parasites within it. Ehrlich tells us that poikilocytes are the products of a fragmentation of red blood corpuscles which can be produced experimentally by heating They exhibit movement and were regarded by Klebs as amœbæ and similar organisms Now increase of water in the blood and increased metabolism (heat production) caused thereby are the two very agents which we know, from experiment, give rise to the appearance of these bodies in the blood. The changes produced in corpuscles by these agents, as described by physiologists, I give below and in a parallel column for convenient reference some of the more usual appearances of malarial parasites as described by Laveran and others

Physiologists tell us :—	Experts tell us :—
1 If water be added to normal blood the red corpuscles lose their discoid form become spherical swollen and dropsical the hæmoglobin is washed out of them and ultimately they disintegrate and disappear	1. The red corpuscles attacked by the parasites are usually the larger ones They lose their discoid form, become spherical swollen, and dropsical, they lose their colour and hæmoglobin and ultimately are destroyed
2 If blood be heated vacuoles are produced in the red corpuscles which appear as little clear colourless shining spots that assume spherical annular, or other form They change their form they increase in size till they occupy half two-thirds or the whole of a corpuscle. They exhibit apparent amœboid movement from contractions in the surrounding hæmoglobin, and they throw out little beaded prolongations which wave to and fro There may be one or more vacuoles in a corpuscle	2. Malarial parasites appear in the first instance on or in the blood corpuscles as little clear colourless shining spots of various forms, spherical annular, or other They change their form they increase in size until they occupy most or the whole of a corpuscle They exhibit amœboid movement and throw out flagella There may be one or more parasites in each corpuscle
3 If blood be heated the white corpuscles, which may or may not contain pigment exhibit amœboid movement and Brownian movement of the contained pigment Quinine paralyses the movements of the white corpuscles and reduces their number	3 The larger spherical pigmented parasites exhibit active amœboid movements and their contained pigment exhibits active swarming movement. Quinine kills the parasites and removes them from the blood
4 The result of addition of water to blood and exposure to increase of temperature is wholesale destruction of red corpuscles and production of pigment free and inclosed in spherical or various shaped bodies	4 The result of invasion of blood by the parasites is wholesale destruction of red corpuscles and increase of pigment free and inclosed in spheres crescents, &c

From the above it can be seen how increase of water in the blood will produce bodies closely resembling parasites—in fact, pseudo parasites The crescent-shaped bodies have been the subjects of much controversy Ross, if I remember rightly, attributes their transformation and flagellation to abstraction of water from the serum and says that this is the influence to which they are exposed in the stomach of the mosquito This opinion he formed as the result of many beautiful experiments. Marshall, on the contrary, after many similar experiments arrived at the conclusion that the transformation and flagellation of the crescent-shaped bodies are due to the addition of water to the serum and says that this is the influence to which they are exposed within the stomach of the mosquito Although they differ, then, as to whether it is reduction or increase they agree that the transformation is due to some variation in the quantity of water in the blood such as I have shown to be the result of exposure to a certain definite environment.

Increase of water in the blood, then, caused by environment produces bodies in the blood which the best experts admit closely resemble parasites and which none but experts are capable of distinguishing from them.

When critical elimination of water (sweat) reduces the amount of water in the blood to normal the pseudo-parasites will disappear, or perhaps it would be more correct to say that the corpuscles which have not been destroyed will resume their normal appearance gradually This production of pseudo-parasites during each paroxysm of an intermittent fever and disappearance during the apyretic interval would of course render more difficult the differentiation of parasitic from non parasitic ague except by experts The establishment of the theory that there is an intermittent fever due to environment would, however relieve Laveran s supporters from the difficulty of explaining how those cases in which no parasites can be discovered in the blood can possibly be caused by parasites. Moreover the presence of pseudo-parasites in the blood of such cases would enable us to understand the assertion of those who maintained that the bodies they found in malarial blood were not parasites at all but simply altered blood corpuscles. Manson says that the staining process for diagnosing malaria is not to be depended on unless carried out by those with great experience.

IX.—INCREASE OF WATER IN THE BLOOD WILL PRODUCE ENLARGEMENT OF THE SPLEEN

As we have seen increase of water in the blood increases hæmolysis or the destruction of red blood corpuscles. But the taking up and disposal of the fragments of disintegrating red blood corpuscles is the normal function of the spleen. Hence when increase of water in the blood produces increased destruction of these corpuscles increased functional activity of the organ and therefore increase of its size or bulk follows Moreover the increase of water by increasing the volume of the blood will of itself also directly tend to enlarge the spleen.

When critical elimination of water (sweat) occurs there is of course diminished volume of the blood, diminished destruction of red blood corpuscles, and consequently diminished functional activity and size of the organ which is normally called on to dispose of the disintegrated corpuscles Hence in the apyretic intervals the spleen resumes normal size. But if this intermittent increase of water in *the blood is frequently repeated the organ will become* permanently enlarged for it is known that transitory but repeated hyperæmia of any organ leads to a permanent enlargement of the organ, such as is found in ague cake, in those suffering from chronic malaria.

Now this view that the enlargement of the spleen is in some cases of intermittent fever at all events due to the intermittent excess of water produced by *meteorological* environment receives some support from a consideration of the periodical change in size of the organ that takes place in health In health it is known that the spleen enlarges to some extent after every meal reaching its maximum after some hours and then returning to its normal size When food is taken into the stomach the first portion of it to be absorbed is its water which enters the blood directly through the gastric vessels. This addition of water of course, increases the volume of blood, and also destruction of blood corpuscles, thus leading as described above, to the enlargement of the organ. This rapid absorption of water of the food by disintegrating and so getting rid of the old and useless blood corpuscles prepares the blood for the pouring into it some hours later of the other constituents of the food *viâ* the longer route of the intestinal lacteals and thoracic duct.

Another point which supports this view of the cause of enlargement *of the spleen is that whatever other medi*cines, &c, we may also employ a free use of hydragogue purgatives is indispensable for the reduction of the organ to its normal size. Is not this an indication that in the first instance its enlargement is due to increase of water in the blood?

The spleen is enlarged in ague then because in this disease there is increased destruction of red blood corpuscles the disposal of which in ague, as in health is the normal function of the organ, and the increased destruction of corpuscles is produced by increase of water in the blood.

X.—THE MEASURES FOUND MOST USEFUL IN THE PREVENTION AND TREATMENT OF AGUE REDUCE CONSIDERABLY THE AMOUNT OF WATER IN THE BLOOD.

Prevention.—Drainage of the soil in paludal districts undoubtedly eradicates or at least considerably reduces the prevalence of ague The most obvious effect of drainage is, however that it dries the soil and therefore the superincumbent atmosphere Drainage removes or at least reduces one factor (atmospheric humidity) of the environment that produces increase of water in the blood In well built, well raised houses the humidity of the air is less than in the *open, and those occupying* such houses are therefore less likely to contract the fevers to which I am referring than those who are liable to exposure at night. The same may also be said of residence in huts tents, or even within mosquito curtains.

Treatment—All effective treatment of ague reduces the amount of water in the blood. Diaphoretics, diuretics, and purgatives certainly *do so. And it is to this that I attribute* the curative and indeed, preventive action of quinine When ague becomes chronic a course of Turkish or *dry* air baths is most beneficial and what so obviously reduces the amount of water in the blood? Removal from the influence of the meteorological environment that produces increase of water in the blood usually cures ague

XI.—SUMMARY

What I have written above may be shortly summarised as follows 1 Cases of fever clinically identical with malaria, occur in the blood of which parasites could *not* be *found* after repeated search before quinine had been given. 2. The meteorological environment found where such cases occur and indeed in all malarial climates increases the amount of water in the blood of those exposed to its influence by impeding elimination through the skin and lungs (evaporation—heat loss) and through the kidneys. 3. There is known to be increase of water in the blood of those suffering from ague (Liebermeister) 4. Increase of water in the blood increases metabolism—i e. heat production—and produces a rise of body temperature (Payne). 5. As environment thus causes diminished heat loss from the body and increased heat production within the body it is plain that it causes pyrexia. 6. This pyrexia must be of intermittent variety as the environment which produces it is of intermittent intensity—i.e undergoes diurnal variation 7 Elimination of water from the blood (sweat) in ague reduces the temperature to normal 8 Increase of water in the blood produces poikilo*cytosis pseudo-parasites liberation of hæmoglobin, extensive* destruction of red blood corpuscles, and melanæmia. 9 An extreme degree of these changes obviously leads to hæmoglobinuria. 10 Increase of water in the blood produces enlargement of the spleen 11. Removal from the environment that produces increase of water in the blood usually cures ague. 12. All treatment of ague which is efficacious reduces the *amount of* water in the blood. 13. From these facts I think it is not unreasonable to conclude that those cases of ague or intermittent fever in which no parasites can be found are demonstrably due to the environment under which they arise.

If my view is correct it is only one more illustration of the truth of the old saying that pathology in many instances seems to be but physiology in distress

RESULTS IN HAVANA DURING THE YEAR 1901 OF DISINFECTION FOR YELLOW FEVER,

UNDER THE HYPOTHESIS THAT THE STEGOMYIA MOSQUITO IS THE ONLY MEANS OF TRANSMITTING THE DISEASE.[1]

BY W C GORGAS
MAJOR MEDICAL CORPS UNITED STATES ARMY; CHIEF SANITARY OFFICER OF HAVANA

IN order clearly to show the results of our work in Havana it may be well to go over the ground and to point out what the conditions were before we commenced work and to look into some general considerations with regard to the habitat of yellow fever When we attribute the results of the work here to our methods of destroying infected mosquitoes it has been objected that yellow fever has disappeared from many other cities under other methods of disinfection and when no particular effort was made to stamp out the disease, and instances are cited of cities of the United States such as Boston Philadelphia New York and New *Orlean* and some of the smaller towns in the West Indies Mexico, and South America.

Havana is unique in being the *only city* in the Western

---

[1] A paper read before the International Sanitary Congress held at Havana, Cuba, on Feb. 15th 1902.

Continent where yellow fever has really always been endemic during historic times, and when we come to look into the matter the reasons are obvious In any community where frost occurs yellow fever will always disappear during the winter Even in our Southern ports, such as New Orleans, Mobile, and Pensacola, yellow fever habitually disappears at that period Incidents might be adduced of its persisting through the winter, but such instances are rare. The natural tendency of these cities would be to free themselves of yellow fever if re introduction from the outside is prevented In the smaller towns within the tropics, those having a non immune population of, say, 50, the same tendency is observed from other causes. While yellow fever would not die out from climatic conditions, in the course of a year or two these few non-immunes would disappear as non immunes either from death or by becoming immune from having had yellow fever, and the tendency would be for this disease to disappear and to re-appear when the population had again become non-immune to a considerable extent. This is really the history of the disease as observed Of course, the larger the non immune population in the tropics the longer the epidemic period lasts, sometimes many years Even cities of the size of Vera Cruz and Santiago de Cuba are not truly endemic foci in the same sense that Havana is Looking back over the history of these cities many years at a time can be found in which there was no yellow fever, and if introduction from the outside could have been prevented they would have freed themselves from yellow fever from the above causes In Havana the conditions have been different it is the principal port of entry for Cuba and there has been a considerable influx of non-immune Spaniards—from 4000 to 30,000 annually Theoretically, from the existing conditions we would expect that yellow fever would be endemic in Havana, and as a matter of fact as far back as the records go from which any at all reliable history of the statistics of the city can be obtained a month has never passed until the American occupation without a death from yellow fever And there has probably in all this time never been a day on which there was not a case of this disease in Havana. This is the only city in the world of which that can be said. Probably Rio de Janeiro can in future be placed in the same category Its large population, large immigration, and latitude would seem to make the conditions very similar to those of Havana.

I go over this ground to show that the causes which have made yellow fever disappear from other cities in all latitudes of the Western Hemisphere cannot occur in Havana The statistics of yellow fever for Havana, as far back as we have official record, are given in the appended table and show the deaths from this disease month by month

When we commenced work in Havana the island had been suffering for five years from an exhausting civil war and during the few months preceding the city had undergone a blockade by the American fleet. The hygienic conditions of the city were therefore at that time considerably worse than they were in normal times. But the non immune population was small, immigration had dwindled during the war and had practically stopped for the year preceding We went to work on the usual sanitary lines with our efforts directed more particularly toward yellow fever I will not attempt any description of the general sanitary work but will enumerate the methods adopted towards yellow fever

Up to July of the first year of American occupation there was little yellow fever in the city Then immigrants began to pour in and some 16,000 reached Havana between July and Dec 31st in the year 1899 From July to Dec 31st we had quite an epidemic of yellow fever, and the December of 1899 was the severest December as regards yellow fever that had occurred for years In February, 1900, I was appointed the Chief Sanitary Officer of Havana and I know from personal observation that from that time the regulations with regard to yellow fever were carefully carried out

The reporting of yellow fever was compulsory Upon the report of a case it was promptly isolated and quarantined by guards employed by the Sanitary Department No communication whatever was allowed within the quarantined area except that of the visiting physicians and the sanitary inspector All supplies had to pass through the sanitary guard. The isolation was as complete as military authority and liberal expenditure could make it The case was then referred to a board of experienced physicians who visited the patient and made the diagnosis If the case terminated in death the body was buried with the usual sanitary precaution adopted in highly dangerous diseases In all cases the quarantined area was disinfected. First, by carefully ing down everything with a bichloride solution and then

by filling all rooms with formalin gas, using a litre of the 40 per cent. solution to each 1000 feet of space disinfected. Fabrics of all kinds were taken to the steam disinfecting plant and there disinfected. Under this system we hoped to decrease yellow fever greatly and in the course of a few years to eradicate it from the city

The general sanitary measures adopted appeared to be rapidly decreasing the general death-rate. The general death rate in 1898 was 91·03 per 1000 in 1899 it fell to 33·67 and in 1900 continued to decrease to 24 40 But our work apparently had no effect upon yellow fever The winter epidemic of 1899 continued through the spring and summer, reaching in the fall the proportions of a sharp epidemic, even for Havana. We had during the year 1900 1244 cases of yellow fever with 310 deaths. All classes suffered, particularly the higher officials on the military governor s staff. The chief quartermaster of the island, the chief commissary for the island, and one of the aides of the military governor died from yellow fever

The Sanitary Department was much discouraged at the result of the work. It seemed to me that general sanitary measures could not be more extensively carried out than we had done during this year We had all the power of the military authority behind us and ample means During this year on the internal sanitation of houses, exclusive of street-cleaning disposal of garbage &c., we spent about $25,000 per month and employed some 300 men daily The general sanitary conditions were improving in the most satisfactory manner but we evidently had not produced the slightest effect upon yellow fever We commenced 1901 much discouraged, with the most unfavourable outlook as far as yellow fever was concerned. The non immune population was larger probably than it had ever been before. 26 000 immigrants had come into Havana during the year 1900 Yellow fever was in every part of the city The deaths from yellow fever in January and February were large and the probabilities all pointed to our having a more severe epidemic in 1901 than in 1900

The results of the investigations by the Army Board of the theory that the stegomyia mosquito was the only carrier of yellow fever first advanced by Dr Charles Finlay were published about this time. This work was so brilliant in its execution and so positive in its results that, as I look back now I am surprised that I was not at once convinced. But many years of contact with men engaged in the practical work of managing yellow fever and my own personal experience with this disease had so impressed me with the belief that fomites were the principal and practically the only carrier of the disease that I had scant belief in the mosquito theory But General Wood was determined that every possible measure should be taken for the reduction of the disease and he authorised me to go to any reasonable expense in providing for the destruction of mosquitoes, which I then considered only a possible and exceptional means of transmitting yellow fever But having undertaken it the department bent every energy to carrying it out thoroughly and as I look back I have the satisfaction of believing that we could not have carried it out more thoroughly even if we had known that the results would be what they have been.

In looking over the ground beforehand we concluded that for practical operations three fields of work had to be considered In the first place, to destroy all the stegomyia we could, so as to limit the number of insects capable of conveying the disease For it seems obvious that if we had no stegomyia we would have no yellow fever In the second place, to prevent the stegomyia from biting the yellow fever patient, because, if we could prevent the mosquito from becoming diseased we would also prevent yellow fever And in the third place to destroy all mosquitoes that had bitten yellow fever patients and thus become infected because if these are destroyed it is evident that the disease would be stopped.

With the object of reducing the number of mosquitoes an ordinance was issued requiring all people within the city limits to keep receptacles containing water mosquito proof. The city was divided up into districts and an inspector was appointed for each district who kept up a constant inspection, with the view of enforcing these ordinances. He was accompanied by men with oil-cans to pour oil into all puddles, cess pools, &c., about the dwellings and after sufficient notice had been given all receptacles in which larvæ were found were destroyed. All persons having larvæ on their premises were fined under the municipal ordinances. 50 men were employed in this work. 100 men during most of the summer were employed under proper superintendence in the suburbs, draining all pools and low ground and pouring oil into such places as could not be drained—that is during most of the past summer 150 men devoted their attention to killing mosquitoes in the larval stage.

To meet the second proposition—that is to keep the stegomyia from biting the infected man—all hospitals where yellow fever was received were ordered to be thoroughly screened, and this was at first enforced. In cases of yellow fever occurring in private houses the sanitary department screened them at public expense. Ordinarily within two hours after the report of a case of yellow fever the quarantined area was thoroughly screened. We kept a sufficient number of ready made screens on hand for the purpose and 30 men were employed in this work.

To meet the third proposition—that is, killing the infected mosquitoes—the infected building and all adjacent buildings were gone over from top to bottom with pyrethrum powder, 150 pounds on the average, were used in each case. This work was done in addition to the disinfection as carried out the preceding year While pyrethrum powder is not as good a mosquitocide as some other substances it is the least objectionable to the people whose dwellings are being fumigated. It causes no injury to fabrics and within four or five hours the room can be again occupied without discomfort. It, however does not kill all mosquitoes A good many of them are simply intoxicated and will revive if exposed to fresh air For this reason the mosquitoes have to be carefully swept up and destroyed. The houses contiguous to the infected house were gone over in the same way on the possibility of infected mosquitoes having escaped to neighbouring houses. Every room was carefully sealed and pasted just as we had done in using formalin. In this work some 40 men were employed during the summer We used a pound of pyrethrum powder to each 1000 cubic feet of air space.

In January 1901 we had 24 cases of fever with seven deaths—a large number for that month, in February there were eight cases and five deaths.

The mosquito work was inaugurated on Feb. 27th We went through March with only two cases, which occurred on the 2nd and 8th. I was much pleased with this but not particularly impressed, knowing that it might be a coincidence. We then went to April 20th without another case. This was unexpected particularly as the year had commenced so badly and as there was plenty of non immune material around The table will show that this condition of affairs had never been approximated before in Havana. On April 21st and 22nd there were two more cases, but under our system of disinfection the disease did not spread. I began to feel pretty certain by this time that the results were due to our mosquito work. On May 6th and 7th we had four more cases, but this focus was promptly controlled. We then went through the whole month of June up to July 21st before we had another case.

It was exceedingly important to have all cases reported so as not to let a focus get started and spread. A great element in the reporting of cases was to have as little opposition as possible on the part of the people. The fumigation for the mosquito caused very little inconvenience compared with the disinfection of fomites and after much discussion and deliberation with the officers in charge of the disinfecting work I determined, the latter part of June to do away with all sanitary measures against yellow fever except those directed towards the mosquito as the only means of the transmission of the disease.

These measures went into effect on July 1st and after that time nothing was sent to the disinfecting plant in yellow fever cases and at the infected point only measures looking to the destruction of mosquitoes were taken. The guard was still kept at the infected house, but the physician was allowed to specify a reasonable number of immunes who might go to and from the quarantined area. The guard was directed to see that the screen doors were kept closed and that the ordinary sick room hygiene was carried out.

About the middle of June a pronounced focus of yellow fever developed in Santiago de las Vegas a town about 12 miles from Havana. The successful management of this focus was another evidence of the efficacy of the methods adopted in Havana, but the length of this paper does not allow me to go into details of these cases. Santiago de las Vegas is a town of 5000 inhabitants, with a non immune population of 475. It is really a suburb of Havana and considerable numbers of people come and go every day Besides Santiago de las Vegas there were three or four other towns with direct communication that were having yellow fever about this time. We discovered nine cases that came into the city of Havana from Santiago de las Vegas during June, July, and August. As Havana had been entirely free from yellow fever during June I am inclined to think that Santiago de las Vegas was the point from which we became reinfected During July we had four cases in Havana, with one death, during August we had six cases with two deaths Becoming satisfied that we were being reinfected from outside towns I obtained authority from the Military Governor to place inspectors on all railroads coming into Havana from infected points These took the names of all the non immunes coming into the city and kept them under observation for a week. This worked very well in practice. All the cases known to have come into the city were reported by these inspectors

As the infection was severe in Santiago de las Vegas an appropriation of $4000 was made for the purpose. We adopted the same methods there as in Havana and at once controlled the disease The last case occurred in Santiago de las Vegas on August 31st A case from this point was reported on Oct 14th, but I, personally, do not think it was a case of yellow fever It was an exceedingly mild and doubtful case, though diagnosed as yellow fever by the board. On Sept 28th we had our last case in Havana. During October, December, and January we had none

The whole year has been very unusual in its yellow fever conditions and is far below any preceding year of which we have record in the number of cases which have occurred October and November have always been months when yellow fever was rife in Havana, and to have had none at all in these months in 1901 is remarkable During 1900 the general death rate had been greatly lowered by the sanitary work done, but yellow fever had not been much affected and we had a sharp epidemic In 1901 all the conditions were unchanged, except that work for the destruction of mosquitoes was carried out, with the result that yellow fever at once almost disappeared and really did disappear in the last three months of the year

I submit that this is evidence of the practical demonstration of the mosquito theory

Havana.

CASE OF RIGHT AORTIC ARCH WITH ABNORMAL DISPOSITION OF THE LEFT INNOMINATE VEIN AND THORACIC DUCT

BY S CAMERON,
JUNIOR DEMONSTRATOR OF ANATOMY, GLASGOW UNIVERSITY

FEW parts of the human body are subject to such interesting abnormalities as are the pulmonary artery, the aorta, and its branches, and since the researches of Rathke, Allen Thomson, and others it has been possible to account for and to classify the vast majority of these abnormalities on embryological grounds It will be remembered that in the early fœtus the dorsal aorta is formed by the junction of the fourth arches on the right and left sides, and that a great portion of the fourth right arch afterwards disappears, the remnant forming the right subclavian artery, while the fourth left arch becomes the arch of the aorta The fifth right arch also disappears, whilst the fifth left arch is represented in the adult by the pulmonary artery and by the ductus arteriosus connecting that artery with the aorta The causes of variation from the normal are obscure, but it is a natural supposition that when inflammation or obstruction affects those vessels which should normally persist and causes them to atrophy compensation will be brought about by an increase in the size of the corresponding vessel on the opposite side. A certain degree of inherent instability in the development of the fœtal vessels must also be considered as existing apart from pathological causes.

The subject of the present irregularity was an adult male The position of the heart was quite normal and there were no irregularities of its valves, septa, arteries, or veins The ascending aorta, which was somewhat large, arose from the base of the left ventricle and took a course upwards and to the right, passing behind the sternum, crossing the trachea until it reached the level of the second dorsal vertebra on the right side. It here bent acutely backwards on itself, thus coming in contact with the right side of the third dorsal vertebra. The vessel was now directed gradually towards the middle line, but when it reached the level of the upper border of the seventh dorsal vertebra it described a gentle curve with the convexity towards the right side, till it reached the middle line between the twelfth dorsal and first lumbar vertebræ It will thus be observed that the vessel in its course arched over the root of the right lung The main arterial trunks were given off in the following order — (1) left common carotid, (2) right common carotid, (3) right subclavian, and (4) left subclavian It will be observed that the innominate artery was absent. The left common carotid was somewhat larger than usual and measured 14 centimetres from its origin to its bifurcation The right common carotid measured 11 centimetres These vessels pursued a normal course, as did also the right subclavian artery The left subclavian presented some points, however, which are of much interest, as noted above it was the last of these vessels arising from the aorta. Its origin was from a pouch like process projecting from the left side of the descending aorta. This pouch measured one and a half centimetres in length and equalled a normal common iliac in diameter It ran to the left side at right angles to the aorta, having the third dorsal vertebra behind it, while the posterior surface of the œsophagus rested on its anterior wall. This pouch presented several undulations on its posterior and under wall. At the point where the subclavian took its origin from this pouch the ductus arteriosus, which was very well marked and of large size, joined the pouch, thus connecting it with the left pulmonary artery The ductus arteriosus measured four centimetres in length. It was quite impervious and lay to the left of the œsophagus The pulmonary arteries were normal both in their relations and distribution. The subclavian after arising from the pouch ascended to gain the inner margin of the scalenus anticus There were two left bronchial arteries arising from the dorsal aorta, the left (upper) arising by almost a common origin with the fourth left intercostal artery There was one right bronchial artery which also arose from the front part of the descending aorta. The left innominate vein was of large size and began behind the inner part of the clavicle In its descent it passed forwards and inwards and came to lie immediately in front of the origin of the left subclavian artery from the

pouch. It passed from here under the arch of the aorta and united with the right innominate vein at the right side of the arch of the aorta to form the superior vena cava, which opened as usual into the right auricle. Its tributaries were quite normal. The other venous trunks in the mediastina were normal. The left upper azygos vein was of small size. The left vagus nerve, descending in front of the left subclavian artery passed between it and the left innominate vein, and then took up its position behind the root of the lung It gave off the left recurrent laryngeal nerve immediately below the junction of the ductus arteriosus and the pouch from which the subclavian was derived. This nerve passed upwards and inwards curved round the ductus arteriosus and after passing superficially to the pouch it gained the space between the trachea and œsophagus and pursued a normal course to the larynx. The right vagus nerve crossed in front of the aortic arch supplying a right recurrent laryngeal nerve the course of which was in every way normal. The right vagus as usual passed behind the root of the lung The thoracic vertebræ described a convexity towards the right side which fact has also been noted in cases of right aorta by Otto and Turner and so that it would support the argument of those anatomists who hold that such a curve is not formed by impulses transmitted to it from the aorta. The thoracic duct in its entire extent lay in the left posterior medastinum, at no point passing to the right of the middle line its termination was normal in all respects. *There was no transposition of the viscera*

The case which is here reported is of rare occurrence and represents atrophy of the fourth left arch with persistence of the right arch and right and left aortic roots. In Sir William Turner s able article in the *British and Foreign Medico-Chirurgical Review* vol. xxx 1862, he divides the class of case which is being dealt with into three groups according to the variations in the condition of the fifth left vascular arch. In his own words It will therefore be advisable to consider them under distinct heads which will be distinguished from each other by different states of the ductus arteriosus—(1) cases in which the ductus arteriosus is quite patent (2) cases in which the ductus arteriosus is atrophied to a mere fibrous cord (3) cases in which the ductus arteriosus is altogether absent.' This case comes under the second head, and is similar to cases reported by Fiorati and Sandifort[1] by Mr Ewen[2] and by Sir William Turner[3] A similar case is also figured in Quain s Plates.[4] The present case corresponds as far as the arterial distribution is concerned with that of Sir William Turner The chief point of difference is in connexion with the left innominate vein This vein bears a relation to the aorta, as will be observed above which I do not think has been noted in connexion with any irregularities of the aorta or its branches or even in subjects in which the arterial system is quite normal. The course of the ductus thoracicus, which *was wholly in the left posterior mediastinum, is stated by* Quain to be a very rare occurrence. In the cases of right aortic arch previously recorded no such course of this duct has been ob erved, so far as I am aware. The explanation of the arterial irregularities will be readily understood from the accompanying diagram but the course of the innominate vein cannot be so easily explained It is probably not a point of much embryological importance as in the embryonic condition the left innominate vein is merely a communicative branch and not a primary venous trunk

Some of the points which should be noted in this case are—(1) the arching of the aorta over the right bronchus and its descent for the most part in the right posterior mediastinum (2) the absence of the *innominate artery* (3) the origin of the left subclavian artery from the pouch like trunk on the left side of the descending aorta (4) the fact that a vascular circle is formed round the trachea and œsophagus, and (5) the large but impervious ductus arteriosus uniting the pouch and left pulmonary artery

These points were all noted in Turner s case but in no cases of right aortic arch has the peculiar course of the left innominate vein under the arch of the aorta been noted as in the present case and the rare course of the thoracic duct through the left posterior mediastinum is also worthy of notice.

Glasgow

THREE CASES OF ACTINOMYCOSIS

BY PENRY W ROWLAND M B. LOND ,
LATE RESIDENT SURGEON ROYAL SEA-BATHING HOSPITAL, MARGATE

THE occurrence of three cases of actinomycosis at one time in a hospital of 150 beds is sufficient reason for reporting them for the disease is still considered rare.

CASE 1.—A London policeman, aged 22 years was seized with acute pain in the right iliac region on April 28th 1900 He was admitted a week later into the Westminster Hospital. After nine days an abscess was opened which was considered to be due to suppurative appendicitis. During the next eight months several incisions were made in the loin and back and in the neighbourhood of the original incision which showed no sign of healing A dental abscess was also opened. As no evidence of the presence of actinomyces was discovered the disease was at length supposed to be of tuberculous origin. On admission to the Royal Sea Bathing Hospital Margate, on Dec. 3rd several indolent sinuses were present in the right iliac fossa and in the right loin, from which there was a slight amount of discharge containing actinomycotic granules. On the 25th dulness was found on percussion at the right base. Exploration proved the absence of effu ion At the left base auscultation revealed small patches where the lung tissue appeared to be breaking down. A week later cough came on and in a few days two or three pints of purulent sputum containing abundant granules were expectorated without any change in the signs at the right base. The fungus was soon afterwards discovered in pus pressed from a small sinus by,the side of a carious bicuspid. During the next few months emaciation steadily increased accelerated by several attacks of diarrhœa. Blood was present in the stools from time to time, but granules were not detected until August, 1901. Incisions were repeatedly made into new subcutaneous collections of pus in the back Hæmorrhage was always free on these occasions and tended to persist, especially from one sinus which passed deeply *into the region of the left kidney The presence of the* fungus was readily demonstrated in each new abscess Pain in the head and across the loins and hips was marked at times and survived all drugs but morphia. Progress was constantly downwards until death occurred on Nov 20th Several three-week courses of iodide of potassium were given (90 grains daily) without any evidence of beneficial effect indeed the patient s general condition was always worse during the use of this drug The sinuses were occasionally opened up and pure carbolic acid was applied. Surgical treatment of a more radical nature was not possible.

At the post-mortem examination it was found that the lower lobe of the left lung was congested and that there were old pleural adhesion. In the left lower lobe the pleura was *adherent in places where there were several small sinuses* connecting abscess cavities in the back with deposits of the fungus close to the surface of the lung Protruding above the surface in the vicinity were several actinomycotic colonies about a quarter of an inch in diameter Infection of the lung had apparently taken place through the thoracic wall The capsule *of the left kidney was adherent below* and behind where there was an abscess cavity leading through the left loin to the surface. There were three deposits of actinomyces in the lower third of the organ, the pelvis of which contained pus. The appendix except for adhesions, was normal No ulceration was found anywhere in the small or large intestine, a few granules were present throughout, free in the lumen of the bowel *The right iliac* abscess was entirely retro-peritoneal and communicated with the sinuses in the back Advanced lardaceous change was found in the liver spleen, and kidneys

CASE 2.—The patient was a London coalheaver aged 27 years. His illness began in the middle of September, 1900 with pains in the right side, right loin and groin whilst walking Constipation was troublesome. He was admitted to the London Temperance Hospital on Nov 2nd with an indefinite swelling in the right side of the abdomen. In mid December there was a definite tumour of the size of a closed fist to be seen and felt in the upper part of the right iliac fossa. On Dec. 27th an inci ion was made over the iliac crest, which appeared to be bare and pus escaped. The patien had gained four and a half pound in weight si e admis sion. There was pyrexia throughout January and steady loss of weight. Early in February another fluctuating swelling appeared in the right groin and from this two ounces of pus were evacuated At the end of February the temperature was always above normal. On the 25th granules were detected and the patient was at once given 60 grains of potassium iodide daily This dose was soon raised to 90 grains Two months later he was sent to Margate Here he continued to lose ground steadily Several incisions were made in the thigh and back, the escaping pus being highly offensive After a second attack of diarrhœa the patient became very much worse and died with symptoms of general sepsis on May 24th.

---

[1] Museum Anatomicum vol I p 273.
[2] Guy's Hospital Reports 1840 p. 233.
[3] British and Foreign Medico-Chirurgical Review vol. xxx., p. 1862.
[4] Plate vii., Figs. 1 1 b.

At the post-mortem examination the appendix was found deeply hidden beneath coils of adherent intestine and was surrounded by an abscess extending into the psoas and the muscles of the anterior abdominal wall. This communicated with the sinuses in the groin, right iliac region and back Septic peritonitis had followed the yielding of adhesions between the coils of bowel, probably during the recent attack of diarrhœa. There were no granules found anywhere except in the pus in the sinuses mentioned above The mucous membrane of the intestine was apparently healthy everywhere. The liver and kidneys showed fatty degeneration, the spleen was considerably enlarged At the base of the right lung there were recent adhesions and a few ounces of fluid. The latter were caused by perforation of the chest wall from without by an abscess in the back.

CASE 3—The patient, the daughter of an East-end labourer, was 14½ years of age She was admitted to the London Hospital on April 6th, 1900 Abdominal pain and vomiting ushered in the disease early in January The vomiting soon ceased but the pain continued and became worse on March 25th Dysuria was also present On admission a hard swelling was found rising up out of the pelvis and reaching to within two inches of the umbilicus It was situated more on the left than on the right side There was a small lump in the right hypochondriac region. On examination per vaginam the cervix was found to be drawn up The swelling appeared to be connected with the uterus The operation showed the uterus to be normal and the swelling to be confined to the abdominal wall A hard inflammatory condition was discovered with a little pus Temporary incontinence of urine followed the operation and several slight fits occurred the next day Early in May a hard swelling appeared to the right of the median wound On May 16th cultures were made, no tubercle bacilli were found, nor was there evidence of actinomycosis A nightly rise of temperature began in June, but there was little change in the patient's general condition On June 5th the patient was removed to the Royal Sea Bathing Hospital. One or two small, almost translucent, granules were found which on microscopic examination proved to be actinomyces Iodide of potassium was immediately given, 60 grains daily, without effect In July an abscess under the iliac crest was opened but no granules were detected The patient did not gain weight and remained depressed and ill. In the middle of September she was received back to the London Hospital. A new tumour arose in the right iliac fossa and increased rapidly in size until it reached nearly to the umbilicus It was apparently closely connected with the anterior superior iliac spine On Oct 1st the anterior abdominal wall was involved. Leave for operation was refused and the patient was discharged. No granules were recognised during her short stay In December a visit to her home found her under the care of the Canning Town Medical Mission, by whose kindness I was again able to find the fungus in pus from the large abscess which had spontaneously opened A month or two later an abscess was incised in the right loin. Diarrhœa increased the cachexia and in May the patient died after an illness lasting over two years Unfortunately, no post-mortem examination was made.

The following points seem worthy of note First, the resemblance between the three cases and some in the series reported by Mr Godlee in THE LANCET of Jan 5th, 1901, p 3 Secondly, the tendency of the pus to avoid artificial channels and to track or to gravitate towards the loin, free drainage is insufficient treatment. It is conceivable that light hinders the growth of the "fungus" It would be interesting to know the effect of Roentgen or Finsen rays in cases where the skin is involved. Dental surgeons have sometimes opportunities of early diagnosis upon which the life of the patient depends In Case 1 it is probable that the jaw was first infected The necessity for repeated examination of pus in cases of obscure abdominal abscess has frequently been emphasised, so has the uselessness of iodide of potassium in the later stages of the affection In a disease of such malignancy surgical treatment should be radical if drug treatment prove unavailing after fair trial

I am indebted to Mr A. H Tubby, Sir W J Collins, and Dr G E Herman for leave to use notes kindly supplied by Mr H. Halliday and Mr J H Rhodes Mr W. Knight Treves and Dr A. Rowe were in charge of the patients at the Royal Sea-Bathing Hospital, Margate, and gave me ready permission to publish their cases To my successor, Mr R J Lambart Sladen, my thanks are due for completing the notes.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL

CONCERNING THE AURICULAR REFLEX

By WALKER OVEREND, M A., M D OXON,
LATE RADCLIFFE TRAVELLING FELLOW AND SENIOR PHYSICIAN TO THE TOTTENHAM HOSPITAL

IN a short communication from Mr E Donaldson[1] a reflex movement of the auricle of the ear is described which was observed by him in May, 1902. In a case of apparent hyperæsthesia of the external auditory meatus under his care the insufflation of a powder was followed by a movement of the auricle The puffing of air alone was also found to produce the same effect In a paper on the frontal or supra orbital reflex[2] I described, incidentally, this movement which, as a matter of fact, I have observed for several years As therein stated, at times the reflex follows *gentle* stroking of the skin in front of the meatus—that is, in areas supplied by the auriculo temporal nerve The attollens aurem is the muscle usually involved, inasmuch as the movement is generally in an upward direction, and the efferent nerve of the reflex arc is the small occipital. I pointed out that the reflex is more readily obtained in adults by tickling the skin just within the external auditory meatus opposite the tragus The movement is more lively in children and is obtainable in about one third of the subjects examined. I find that although a puff of air from an indiarubber ear syringe, as Mr Donaldson states, is quite effectual, still the quick and sudden contact of a camel-hair brush is much more so To avoid all voluntary movement I direct that the jaws should be kept firmly and tightly closed

A proof of the true reflex nature of the movement is the fact that the *opposite* ear, as a rule, is simultaneously elevated The effect very soon vanishes, it is not possible to obtain it a second time immediately after the first movement. It is necessary to wait for a few minutes before the reflex can be again elicited. Either the will inhibits the movement, or the muscle, as one might indeed expect, since its fibres are seldom active, becomes fatigued After some education and practice the response becomes more lively, more pronounced, and easier to obtain

Clacton-on-Sea.

A NOTE ON THE HISTOLOGY OF X RAYED LUPUS VULGARIS

BY GEORGE PERNET, M R C S ENG, L R C P LOND,
LATE PATHOLOGIST HOSPITAL FOR DISEASES OF THE SKIN BLACKFRIARS, LONDON

I AM indebted to Sir Victor Horsley for the opportunity of examining microscopically x-rayed lupus vulgaris tissue, which was freely excised from the frontal region of a man, aged 26 years, for purposes of Wolff grafting—i.e, with the whole thickness of skin down to the subcutaneous fat. The area had been subjected about six months previously to 14 daily consecutive exposures to the Roentgen rays According to the patient the duration of each exposure was about from 10 to 15 minutes with the tube an inch or two from the head. Briefly the history of the case was that the patch had commenced at the age of eight years, two other patches on the scalp and *inner part of the right thigh respectively* appearing at the same time. (Involvement of the scalp is unusual and deserves to be insisted on here, at some future time I shall examine the diseased scalp tissue.) The patch on the forehead had been scraped then treated with plasters followed by formalin to the fresh nodules As a result of the x raying the parts became inflamed and discharged yellowish-green matter at first, followed by watery oozing It took three months for the area to heal. A few days before the operation by Sir Victor Horsley the patch on the forehead exhibited a certain amount of cicatrisation about the central *parts, but the edges all round presented characteristic* apple-jelly nodules and solid granulomatous infiltration. An examination of portions of the diseased frontal patch cut in paraffin and in celloidin and stained in various ways led to the following conclusions. In the more central parts of the patch the collagen was disjuncted and to some extent disintegrated, especially in the upper layers of the corium, and had undergone a certain amount of collastin change [1] The elastin was sparsely distributed and where present, the fibres were in many instances broken up the greater part of this tissue had, however been destroyed. There was very little of it in the upper part of the corium and none in the papillæ. The sweat glands showed surrounding infiltration and signs of disintegration. The hair follicles and sebaceous glands had also apparently disappeared but in one section a portion of destroyed hair could be seen lying in the sac-like remains of a follicle. The subcutaneous fat cells were in parts irregular and their nuclei were gone in others they were normal A large vessel in this stratum showed thickening of its walls and contained red blood corpuscles and leucocytes, with some emigrated leucocytes outside. In places there was a fibrous change in the upper layers of the corium.

---

[1] THE LANCET August 23rd 1902, p 506
[2] THE LANCET, Jan 25th, 1902, p 219

There were numerous plasma cells in groups and rows in various parts of the sections from above downwards, and some of these plasma cells were even present deep down in the muscle tissue, which in a few isolated instances had been apparently disintegrated by foci of granulomatous new growth *This is an interesting point and may perhaps*, explain why recurrence occurs even after what appears to be thorough scraping and cauterisation. In the same way it may explain the recurrences which occur after exposure to x rays or the Finsen light. For be it noted the sections which I am referring to were not from the obviously diseased periphery of the patch.

The plasma cells themselves did not all appear to stain in as characteristic a manner as usual, the nucleus in some instances appearing shrunken. There were also what appeared to be naked nuclei and daughter plasma cells were also present. The epidermis was preserved but thinned in some sections, absent in parts in others, but the latter was perhaps due to the cutting as it was readily separated from the subjacent corium, which presented here and there a frayed appearance where the epidermis was missing

A CASE OF PARALDEHYDE POISONING

BY ARTHUR H. M. SAWARD M R.C S. ENG. L R.C.P LOND

HAVING had occasion lately to use paraldehyde which caused an erythematous rash I am led to publish some notes of a case that came under my notice where a large dose of the drug was given to a patient by misadventure. The following is the history of the case.

A married woman aged 43 years was suffering from carcinoma of the uterine cervix *and* was *in an extremely* excitable condition from insomnia and delusions, also at night time she was especially noisy and intractable evidently on account of the pain caused by the cancer As she had previously been freely dosed with narcotics and hypnotics it was found necessary to continue the use of such drugs but the administration of morphia or opium was contraindicated owing to the urine being albuminous. The pupils were contracted and the pulse was slow Trional was therefore employed, but as this drug only produced sleep for short periods the following prescription was ordered (the patient at the time being still extremely noisy) one drachm each of paraldehyde and syrup of orange-peel and water to one ounce but by misadventure she was given an ounce of pure paraldehyde at 12 midnight and the error was neither discovered nor even suspected until some seven hours afterwards. Upon being given the incorrect draught the patient struggled violently and was with great difficulty made to swallow it. A quarter of an hour later the breathing became somewhat irregular and the patient's mouth and larynx full of a thick ropy mucus the latter was all swabbed out and the breathing then greatly improved. As the patient was also suffering from bad stomatitis it was now thought that some of the draught (as ordered) had *entered the lungs during the struggling when it was admini*stered. At 1.15 A.M the breathing was still rapid and irregular 32 respirations to the minute, but the pulse was fairly strong (114) the patient, however seemed half choked with mucus, was becoming somewhat cyanosed, and the tongue was very red and swollen The mouth was again swabbed out with relief. The patient was now semi-conscious fairly sensitive to pain but made no voluntary movement. However she was easily roused by shouting pinching &c. The pupils were variable in size but reacted both to light and to accommodation At 2.15 A.M she was given a hypodermic injection of three minims of liquor strychninæ with two minims of tincture of digitalis which greatly improved both the respiration and cyanosis but half an hour later the breathing again became rapid and irregular with long inspiration and short expiration. The lips were pale and the mouth was dry and free from mucus. The pulse was regular *(124)* but the patient was quite unconscious. The pupils were contracted and the corneal reflexes were completely lost. At 3 30 A M the breathing was still shallow more ropy mucus appeared in the mouth the pulse was still 124 but the patient was more conscious and slightly sensitive to pain at this time there was an involuntary slight action of the bowels. After this she became somewhat restless, tossing about and moaning occasionally, the pupils were dilated but not reacting to light. The pulse was good and the respirations were much quieter continuing in this condition until 7 30 A M. when she again became cyanosed, the pulse feeble and rapid and the skin hot and dry with very shallow respirations. At this period of the case the unfortunate mistake in the composition of the draught was discovered but it was then deemed too late to give emetics or to wash out the stomach so amyl nitrite was at once inhaled and five minims of liquor strychninæ were given hypodermically, *followed by a hot coffee enema these* remedies greatly improved both the pulse and respiration but the patient still remained somewhat cyanosed with rapid and shallow breathing She was then given diffusible stimulants in the shape of ammonia and ether with brandy and hot water by the mouth but as these were swallowed with difficulty brandy (20 minims) was subcutaneously administered For some hours she continued in a very drowsy state the temperature reaching 100° F with a pulse rate of 116 and a respiration rate of 28. Still being unable to swallow anything she was given a nasal feed of eggs milk and brandy and a further hypodermic injection of strychnine. Later in the day she was able to swallow liquid but at night the nasal feed and strychnine were repeated. In spite of this she continued to be drowsy throughout the following night, requiring more strychnine early in the morning of the second day but after this she made rapid progress and was *able to take plenty of nourishment by the mouth* The stupor gradually left her and in another 24 hours she had completely recovered from the evil effects of the undiluted paraldehyde.

Dr W Hale White in his book on Materia Medica states that "even large doses do not affect the gastro-intestinal tract heart, or respiration but enormous doses of paraldehyde weaken the action of the heart and kill by paralysis of the respiratory centre He further says that paraldehyde in toxic doses paralyses the anterior cornua of the spinal cord thus it abolishes reflex action and causes paralysis but does not affect nerves of muscles" In the case related above there was never any definite paralysis except for the short time when the corneal reflex was lost neither was there any marked effect on the gastro-intestinal tract No vomiting occurred at any time and the bowels were only opened once slightly in fact, a soap enema had to be given to empty the rectum The most prominent symptoms in the case were those due to the heart and respiration. As the official dose of paraldehyde is given as from half to one and a half fluid drachms I do not think that it is an exaggeration to say that the ounce given by misadventure in the present case may be reckoned as an enormous dose, and I think that it is only due to the inured state of the patient to narcotics and hypnotics that no further or fatal symptoms intervened on this occasion I take the opportunity of reporting this case as poisoning by paraldehyde is rather a rare occurrence and I do not see much mention of it in the present-day text-books

SHEFFIELD ROYAL INFIRMARY

A CASE OF PERFORATED DUODENAL ULCER, CŒLIOTOMY WITH SUBSEQUENT GASTRO JEJUNOSTOMY, RECOVERY

(Under the care of Mr ARTHUR CONNELL)

DUODENAL ulcers are probably not so rare as is usually imagined, for the symptoms are not so definite as are those of ulceration of the stomach When perforation occurs a diagnosis between these two forms of ulceration is hardly possible, but early laparotomy is the only treatment in both conditions

A man, aged 24 years, was admitted into the Sheffield Royal Infirmary on Feb 10th with symptoms pointing to perforation of a hollow viscus For the last 14 years the patient had suffered from gastric disturbance, the more prominent symptoms being epigastric pain, coming on from one and a half to two hours after meals and at times accompanied by vomiting which greatly relieved both the pain and the discomfort. There were well marked dilatation of the stomach and epigastric tenderness, but at no time was Dr W S Kerr (to whom Mr Connell is greatly indebted for these notes) able to feel a tumour More recently the pain had come on immediately after food There had never been any sign of hæmatemesis, jaundice, or melæna The patient had been suffering acutely for a few days before Feb 10th and *had been fed by nutrient enemata.* At about 5 A.M that morning he was seized with a very sudden and acute pain in the epigastric and right hypochondriac regions and became exceedingly restless, sweating profusely He was seen soon after by Dr Kerr who on examination diagnosed ruptured ulcer, and with as little delay as possible sent him to the infirmary On admission it was seen that the man was suffering from shock and was evidently in great pain The pulse was 108 and soft, the temperature was 96° F, the face was pinched, and the respirations were thoracic The appearance of the abdomen was "full" but with no apparent movement, and on gentle palpation the recti in the epigastric region were held quite rigidly, this manipulation evidently causing the patient increased discomfort. The liver dulness was not obliterated although there was increased resonance over the whole abdominal surface

An operation was performed at 10 15 A M on Feb 10th Ether being administered an incision was made in the middle line, beginning below the ensiform cartilage and continued down for about three and a half inches. On opening the peritoneal cavity the stomach presented and was found to be distended. There was in addition well-marked gastroptosis The liver was now gently raised so as to expose to view the right third of the stomach and duodenum, with the next inspiration gas was seen to escape, being evinced by the bubbling of the extravasated mucus, &c There were no adhesions The surrounding area was immediately cut off from the general cavity by sterilised gauze. The liver being held up the stomach was gently drawn downwards and to the left when a circular perforation, about a quarter of an inch in diameter, was found in the first part of the duodenum towards its upper and posterior surfaces The pyloric portion of the stomach was considerably thickened and a probe passed through the perforation into the stomach demonstrated an exceedingly narrow pyloric orifice. After carefully cleaning the area by mopping the perforation was closed by a double row of fine silk sutures A light gauze drain was placed in position, beginning near the closed perforation and carried out through the wound superficially It was removed 36 hours afterwards The abdominal wall *was closed in the usual manner except where the gauze* drain issued Before closing the abdominal wound the flanks were carefully inspected but no trace of fluid or recent lymph was found

There was nothing of special interest to note in the progress of the case after this operation The patient was fed by nutrient enemata and was allowed small quantities (two drachms) of water by the mouth, his thirst being quenched by saline injections per rectum Two weeks after the operation he was allowed soft bread crumbs and milk and his diet was gradually increased but never exceeded boiled fish Up to March 22nd the patient *progressed very favourably*, but in spite of a restricted diet there was discomfort never amounting to pain. On examination there was still evident dilatation of the stomach Given, then, the patient's discomfort on such a diet and his desire to eat more solid material, with the conditions found at the operation—viz, pyloric obstruction of an inflammatory character, with gastric dilatation, *plus* gastroptosis—he was advised to submit to a second operation. On the 22nd, under ether, the abdomen was opened below and to the left of the original wound, through the left rectus which was split longitudinally with the handle of the scalpel Anterior gastro jejunostomy was performed, the patient being kept on the table only half an hour this time He rapidly recovered from the immediate effects of this operation, but, as so often happens after gastro-jejunostomy, he continued to vomit every other day for about a fortnight He left the infirmary on April 24th feeling "first-rate' When seen on June 9th he said that he had put on half a stone in weight and could eat "anything," and had not the smallest discomfort. He certainly looked remarkably well and stated that his work was a pleasure to him

Remarks by Mr CONNELL.—It is somewhat rare for the surgeon to be called upon to operate for perforation of the duodenum caused by ulceration similar to that met with in the stomach, but in the above case not only was there perforation in the duodenum but a condition of the pyloric end of the stomach to which one was easily able to attribute the various symptoms complained of and to urge operative interference after the primary operation for closure of the perforation

Nothing adds to the successful issue of grave lesions of the upper part of the alimentary canal more than the early recognition on the part of the medical attendant of symptoms pointing to such a condition as perforation, and this is such a typical case of its kind that one cannot fail to appreciate the predominant characteristics First and foremost amongst the earlier symptoms which should not be lost sight of in this or any other case are the presence of pain of whatever degree—continuous or intermittent—vomiting, and wasting—symptoms which appear to have dogged the existence of this man for 14 years with never an attack of hæmatemesis, *melæna*, or jaundice as far as one can elicit.

These earlier symptoms, coupled with a careful examination of the epigastric region in particular, which will always yield the unmistakeable sign of tenderness, amounting to pain, if the lesion is more intense, must of necessity compel one to diagnose ulceration either in the stomach or just beyond and accordingly influence the future treatment of the case But with the sudden onset of excruciating pain and its attendant shock which profoundly affects the general system there can be only one opinion—perforation Unfortunately, however, there are those who, in spite of such phenomena, fail to make a diagnosis and have recourse to morphia with a view of quieting the patient and so giving them more time to consider the case, which otherwise means a greater chance of general infection of the peritoneal cavity The surgeon is then placed in the hapless position of either refusing to operate on a moribund narcotised patient or attempting an operation which in the great majority of cases must of necessity end in disaster It has been my misfortune quite recently to see the patient in a case of perforation of a small ulcer of the stomach die for want of early surgical interference where the case was seen immediately after the perforation—i.e. if we judge from the history which was absolutely typical a large dose of morphia administered and the friends recommended to wait. The diagnosis was verified post mortem I think the surgeon cannot plead too strongly that morphia should be withheld until he has seen the case, for I hold that the patient will have a far better chance and the surgeon, too is far more likely to make a correct diagnosis, which means that his treatment—operative interference—is more likely to be effectual.

Gastro-jejunostomy was performed here for the following reasons, *especially (1) because of the considerably narrowed* pyloric orifice, (2) the presence of ulceration of the duodenum, and (3) the persistent discomfort felt even after a restricted diet.

HUNTINGDON COUNTY HOSPITAL

A CASE OF ADDISON'S DISEASE, WITH HYPERPYREXIA.

(Under the care of Mr H LUCAS.)

ADDISON'S disease is usually unaccompanied by any elevation of temperature, and therefore the following case is of interest. The very remarkable temperatures recorded would in themselves suggest doubts as to their genuineness especially as the pulse-rate was not increased, but care seems to have been taken to eliminate this source of error For the notes of the case we are indebted to Mr Jehan M Barlet, house surgeon.

A woman aged 39 years was admitted into the Huntingdon County Hospital on April 2nd 1902 complaining of great pain in the region of the kidneys with marked bronzing The patient's brother died two years ago from phthisis, five other brothers being alive and well. She was perfectly well until August, 1898, when she was suddenly seized with acute pain in the back after a hard day's washing This pain radiated round to the epigastric region and was accompanied by diarrhœa and vomiting and a feeling of languidness and later patches of yellow pigmentation appeared which became gradually darker in colour She was in hospital in 1898 but went out fairly well and had been able to get about until August 1901 when the pain increased as also did the pigmentation, and there was a recurrence of the diarrhœa and vomiting

On admission the patient was very bronzed especially about the nipples, axillæ, and face. There was great pain on pressure over the region of the kidneys, especially upon the right side, where there was a tender spot anteriorly corresponding with the right kidney She had slight attacks of headache and dizziness occasionally All the other organs were normal. The urine was normal. There were no cerebral symptoms The bowels were very constipated and there was no vomiting Now comes the extraordinary part of the case. On admission her temperature was 99·6° F but this gradually rose by morning rises and evening remissions to 103·4° on April 8th when she was put on a four hourly chart which showed a temperature of 105·6° at 10 P.M The temperature then kept between 101° and 103° until 2 A.M on the 10th, when she had a rigor with a temperature of 109° followed by profuse sweating and a fall to 100·2 From then till the present time (June 14th) the following temperatures have been recorded 107° 12 times 108° three times 109° seven times 110 six times 111° once and 111·6° once These temperatures were verified by being taken in the rectum so preventing the possibility of faking" Another interesting point is that when these elevations of temperature occurred, which, by the way was usually at 10 P.M or 2 A.M there was no increase in the pulse rate—for instance, in the highest temperature at present recorded in her case the pulse-rate was 68 to the minute and this temperature fell to 100° in half an hour On questioning her as to her feelings she said that she felt as if she were going to die but she felt no pain anywhere.

Remarks by Mr BARLET —The question arises as to the cause of these elevations of temperature. I think without doubt that they are due to some nervous influence, but whether they are caused by irritation of the semilunar ganglion and the sympathetic system, thus acting upon the thermogenetic centre I am not prepared to state and should very much like to hear some opinions on this subject. I have to thank Mr Lucas for permission to publish this case.

Reviews and Notices of Books

Nothnagel's Encyclopedia of Practical Medicine (Diphtheria Measles Scarlatina and German Measles) Edited with additions, by WILLIAM P NORTHUP M.D Authorised translation from the German under the editorial supervision of ALFRED STENGEL, M D London and Philadelphia W B. Saunders and Co. 1902. Pp. 672.

THIS volume is distinguished from others of the series which have so far been published by the substitution of an article on Diphtheria by an American author—namely, Dr W P Northup—in place of a translation of the original article as it stands in the German edition. This departure from the course heretofore pursued has been necessitated by an arrangement entered into by the German author to issue a translation of his article independently of the series. Apart from any sentimental regrets which may attach to a proceeding which severs the traditions of Nothnagel's Encyclopedia on the score of efficiency and completeness there is no reason whatsoever to deplore the change. Dr Northup is an acknowledged authority on the subject of diphtheria, a writer of experience and erudition and his well known association with Dr. Joseph O'Dwyer in the practical development of the method of intubation necessarily imparts a distinctive interest to this article and justifies the honourable inclusion of his name on one of the title pages of a work which among those of other contributors contains the names of von *Jürgensen Immermann,* von *Liebermeister Ehrlich and* Stiker

Confining ourselves for the present to the consideration of Dr Northup's article we may proceed at once to the observation that the method and style which characterise his contribution are thoroughly representative of the best examples of American authorship Free from the hidebound conservatism which detracts so largely from the value of much of our own British medical literature, steadied by the weight of German philosophic thought, and brightened with the leaven of transatlantic originality this article on diphtheria is not only practically and substantially sound, but also delightfully illuminating and suggestive reading After briefly epitomising the history of the disease the author immediately proceeds to the consideration of the various etiological factors which determine its development. The bacteriology of diphtheria, in conformity with the importance and interest which attach to this side of the question occupies the position of honour and the lion's share of the pages devoted to the subject of pathogenesis As the result of the early studies of Klebs Löffler and later of the researches of Roux and Yersin the specificity of the Klebs-Löffler bacillus is considered by Dr Northup to have been established beyond a doubt, for the reason that it has been repeatedly proved to fulfil the conditions required of all organisms if they are to be accepted as specific excitants of infective disease. The respective claims of the monistic and dualistic *schools are considered in some* detail and as representatives of the former school of thought Gorham and Westbrook are freely quoted, and their work on the morphological characteristics of diphtheria bacilli is fully described and illustrated by a plate Westbrook, whose work has been extended and confirmed by Gorham, divides all diphtheria bacilli into three groups—the granular barred, and even staining *Their united observations show* that, as the result of the examination of 2375 cultures taken from persons who were healthy, whether disposed to diphtheria or not, the changes from the solid type develop under the influence of the body fluids of persons immune or becoming so. Interesting as these researches are from the morphological side, they contribute little to our knowledge of the respective virulence of the various types or of the causes which lead to variations in the degree of virulence Although Dr Northup gives guarded judgment in favour of the dualistic theory he is quite fair to the claims of the opposite school, to which, by the bye, he seems shy of applying the term monistic Why this should be it is difficult to understand, the term is a good one and obviates the necessity of a cumbrous paraphrase Moreover, it has been sanctioned by no less an authority than Hueppe himself As a means of distinguishing representatives of the pseudo-diphtheritic and true diphtheritic classes of bacilli the author suggests the following tests A given diphtheria like bacillus which produces little or no acid in bouillon cultures, which shows no, or only atypical polar granules in a 12 to 24-hour old blood serum culture, and is non pathogenetic for guinea-pigs, may be safely classified as belonging to the great class of pseudo diphtheria bacilli. These distinctions, though of the greatest practical value in formulating rules, for instance, in regard to isolation and treatment, would probably not be accepted as absolute by the adherents to the monistic theory The pathology and symptoms need not detain us The method in which these parts of the subjects have been handled conforms to the description which we have applied generally to Dr Northup's contribution On the chapter which is devoted to treatment and which adequately describes the results and applications of antitoxin treatment and the operation of tracheotomy it may be safely assumed that the interest of readers will be mainly centred, for in this chapter 15 pages are devoted to the subject of intubation, and it is written with the authority of a co-deviser of the method and by one whose experiences in the developments of the practical uses of the O'Dwyer tube are probably unrivalled. This section of the article is most profusely illustrated with photographs and skiagrams of the method of inserting the tube and of the tube itself *in situ* The technique of the operation is admittedly difficult, but so far as any written description can teach us to apply the method that which is supplied in this volume may be considered as most satisfactorily fulfilling its object. A special section is devoted to the consideration of the question whether tracheotomy or intubation should be the operation of election However, since the combined use of antitoxin and intubation are now so generally considered adequate means of meeting the emergencies incidental to diphtheria there is no need to follow Dr Northup in his vindication of a practice which he has been so largely instrumental in perfecting It is satisfactory, however, to know that in this volume of Nothnagel's Encyclopedia is to be found a very complete and lucid account of the operation.

More than half the space at our disposal for the purpose of this review has already been devoted to the consideration of the article on diphtheria. Apart, however, from the fact that the excellence of the contribution warrants this preferential notice, it is probable that the remaining articles on scarlet fever, measles, and German measles are more or less familiar to our readers either by reason of reviews or by reference to the original German edition The articles which are devoted to these representatives of the group of acute exanthemata are from the pen of Theodor von Jürgensen and they have been translated by Dr W P Northup, who has availed himself in several noteworthy instances of the general permission conceded by Dr A. Stengel, the editor in chief, and by Professor Nothnagel, the editor of the German edition, to make such additions to the original articles as may seem necessary to bring the articles fully up to date and at the same time to adapt them thoroughly to the requirements of American or English readers In the general introduction the possibility of the simultaneous appearance of two or three of the acute exanthemata in the same individual is discussed Various combinations have been recorded by the most careful observers and these cases are fully quoted and should dissipate all doubts which may be entertained of the possibility of this event occurring Moreover, such combinations strengthen the view which is now generally held that measles, scarlet fever, small pox, and chicken pox are distinct diseases which cannot be traced to a common source and which do not represent merely offshoots from one and the same root In no other work with which we are acquainted is the question of combined fevers so adequately described In this connexion the specificity of German measles, or its separate identity from measles, forms the subject of a very interesting disquisition under the heading of "Etiology of German Measles" Von Jürgensen in summing up the evidence for and against the independent existence of the disease asserts that "if we collect all the facts we cannot, in my opinion, recognise the right to independence of the disease which is called rötheln." The translator very properly interpolates at this juncture an editorial note to the effect that Koplik's spots, which occur regularly—approximately 91 per cent—on the buccal mucous membrane, are absent in rötheln. At the present time in England, as in America, measles and rötheln are almost universally regarded as distinct, so that von Jürgensen's authoritative statement as representing a German view on this subject is of considerable interest As an instance of the completeness with which this volume has been brought up to date we notice that the controversy on the question of the individuality of German measles and its relationship to the supposed "fourth disease" has been revised up to the end of last year and actually contains an abstract of an important paper on this question which was published as late as December last. On the subject of the relationship of scarlet fever to puerperal fever von Jürgensen ventures the statement that the former fever in the strictest sense is only an insignificant factor in the mortality of the puerperium and further that the condition described as puerperal scarlet fever is in the vast majority of instances merely a septic infection determining skin lesions similar to those met with in scarlet fever, and with regard to the influence of the specific poison of scarlet fever and that of the secondary infections by streptococci, staphylococci, and pneumococci in the determination of the various lesions incidental to scarlet fever itself von Jürgensen is most guarded in his statements In fact, it is by no means easy to arrive at a real understanding as to whether the author believes that the clinical picture of genuine scarlet fever can be complete without the secondary infections or whether it cannot Interesting, however, as may be these academic considerations, it cannot be claimed that this volume adds very much to our knowledge of the essential causative agents of measles and scarlet fever and of rötheln It is rather in the descriptive account of the symptomatology and in the accurate record of clinical experiences that this volume will be found of real service to the majority of readers

---

Mammals By F E BEDDARD, Vice Secretary and Prosector of the Zoological Society of London Being Vol. X. of "The Cambridge Natural History" Edited by S F HARMER, F R S, and A E SHIPLEY, M.A. With 285 Illustrations in the text London Macmillan 1902 Pp 605 Price 17*s* net.

IT is unquestionably the fact that a volume upon mammals is needed at the present juncture. Since the publication of that still almost, if not quite, indispensable work, "Mammals, Recent and Fossil," by the late Sir William Flower and Mr Lydekker, no general treatise has appeared in English, and it obviously follows that the 11 years which have elapsed since Flower and Lydekker's volume have furnished much additional matter for incorporation into a work dealing with the mammalia. Mr Beddard has not ignored recent work and has indeed perhaps, as is the fashion nowadays, dealt rather more fully with the latest discoveries of science than with the older and more established facts. With extinct creatures this is at times apt to be a little dangerous, a bone here and a tooth there have been occasionally brought into unnatural union and relegated to a creature which subsequent discovery has shown to be non existent the converse however is the more usual course of events, and two fragments put down to beasts of quite different genera or even orders have been found to be the *disjecta membra* of one and the same species, if not individual With such bits and scraps of bones and teeth the author has dealt warily and as we think, rightly so. There is no need to fill up page after page with such dubious remains, at least in a volume which does not profess, and could not pretend to be exhaustive As the author has pointed out, a volume which must fit in with a series in average length must necessarily undergo some compression and be somewhat pruned of detail. The result of this necessary curtailment and compression has been here and there a rather jerky and notebook style. However *stylus virum arguit* (as the author of The Anatomy of Melancholy said long before de Buffon) and Mr Beddard is nothing if not an anatomist to whom the clear presentment of fact is the only essential. And the book must be clearly criticised from this point of view Mr Beddard indeed speaks somewhat contemptuously in his preface of the long stories about lions and tigers which usually *form the main part of works upon natural history* and are believed by publishers, editors, and contributors alike to be the best means of alluring the public This anecdotal portion of the subject is replaced in the volume before us with a few choice fragments from the naturalists of old and especially from those two naive writers of the past, Olaus Magnus Archbishop of Upsala, and the Rev Edward Topsell author of The Historie of Foure footed Beastes describing the True and Lively Figure of every Beast." We cannot forbear from quoting from Mr Beddard the latter naturalist s account of the chase of earthworms by the mole. ' When the wormes says Topsell, are followed by molds (for by digging and heaving they foreknow their own perdition) they fly to the superficies and very toppe of the earth the silly beast knowing that the molde, their adversary dare not followe them into the light, so that their wit in flying the enemy is greater than in turning againe when they are troade upon "

The object of this volume is not, however to amuse the reader with *such matters but to furnish the student with* a handy account of the characteristics of the mammalia. In a large work like the present, dealing with the entire range of the subject, it is hardly to be imagined that there are not some lapses into error The author, for example, has called the polecat by two different names—one in the text and the other in the legend beneath the figure of that animal. Again, the five-horned giraffe of Sir Harry Johnston has been given undue prominence , it has been shown that that animal is not new and that five horns are a character hitherto unobserved of the northern giraffe. But this error is doubtless to be accounted for on the supposition that the paper by Mr Oldfield Thomas of the British Museum was not read, or at least not published at the time that the proof sheets of Mammalia were passing through the author s hands. On the whole it may be fairly said that the volume is free from error as to fact and, indeed the author's opportunities in his laboratory at the Zoological Society s Gardens have enabled him to check or to retail at first hand a large number of facts in anatomy The book is thus not, in one sense at least, a compilation. In another sense, like almost every treati e upon any branch of natural history it is a compilation. In these days of vastly extended knowledge and consequent and necessary specialism it is absolutely impossible for one man to know of his own knowledge all the facts with which he deals in a work even upon so limited a subject comparatively speaking as is that of the volume before us. But where facts other than those which are commonplaces of zoological knowledge are dealt with the author is careful to quote authorities, though the bibliography is not, and could hardly pretend to be anything like exhaustive. The volume contains a large number of illustrations, of which 100 have been drawn specially for the work by Mr Dixon. Most of these are good but the process' system has resulted in a flat appearance which is not altogether attractive. In this they contrast with some excellent woodcuts borrowed from past numbers of *Nature* and offer an instructive example of the failure of any mode of text illustration as compared with the now unfortunately almost decayed art of wood-cutting The figures are perhaps a little too unequally distributed among the groups of the mammalia. The whales, for instance have come off very poorly while the dog tribe has rather more than its share. The anatomical side of the subject is fairly copiously illustrated, a large series of the figures of bones being borrowed from the late Sir William Flower's Osteology of the Mammalia. With such accurate figures available it would have been a waste of money and energy to prepare a new series.

LIBRARY TABLE.

The Diseases of Women a Handbook for Students and Practitioners By J BLAND-SUTTON F R C S Eng and ARTHUR E GILES, M.D Lond F R C S Edin Third edition crown 8vo with 145 Illustrations in the text. London Rebman Limited. 1902. Pp. 527 Price 11s net.—The third edition of this book has been enlarged by 55 pages and the number of illustrations has been increased from 115 to 145 We hope that in the future the authors will attempt to conform to their own statement in the preface to the second edition—viz. that the essential facts of the art can be presented in a very convenient compass, and will avoid as far as possible any further enlargement of what is at present a very handy book. The most important changes are to be found in the chapters upon Uterine Fibroids Extra uterine Pregnancy Ovarian Tumours in connexion with Pregnancy Labour and the Puerperium and Cancer of the Uterus. The term myomata of the uterus has been abandoned in favour of the more generally used but equally inaccurate expression fibroids of the uterus." The chapters upon this subject have been rearranged and considerably added to and amended. In the part of the book devoted to Extra uterine Gestation due mention is made of recent investigations in regard to ovarian pregnancy This section retains the high excellence of former editions We are glad to see that the important subject, cancer of the uterus, has been more fully and adequately dealt with separate chapters containing a number of new illustrations being devoted to cancer of the cervix and of the body of the uterus. Ovarian tumours complicating pregnancy and labour are very fully discussed and the most important part of Mr Bland Sutton s recent admirable lecture upon the subject has been incorporated The book has been well revised and we think, improved and if it still suffers from the marked surgical bias of it authors it is yet a good and trustworthy text book.

A Manual of Otology By GORHAM BACON Second edition, with 114 Illustrations and three Plates. London Henry Kimpton 1901 Pp. 428.—The introduction is by Dr C J Blake and opens for some occult reason at page 17 thereby adding this number of fictitious pages to the volume As an observer Dr Bacon is well gifted but as an analyser he seems to be less so and on reading the book the impression is given that his idea of a manual is the recording of clinical lectures illustrative cases being freely scattered throughout These excellent as they are in clinical teaching, are quite out of place in a book like this, which should lay down precise and definite directions for the diagnosis and treatment of disease Not only is this so but the text is needlessly involved. For example, a portion of the symptoms appear under their proper heading and the remainder are given in other parts At times matter quite foreign to the point under discussion is inserted. An instance of this will be found on page 164 et seq , under acute purulent otitis media is a full description of a case of primary malignant disease with illustrations of microscopical sections and a reproduction of a photograph showing the facial palsy, whereas the mention of the danger of mistaking early malignant disease for acute otitis would have sufficed. Not infrequently the wording and arrangement of the text are such that an impression is conveyed quite different from that which the author intended to give, as in the treatment of acute catarrhal inflammation of the middle ear, where it is recommended in young children to search for adenoids and if present to remove them with the finger nail (p 150), whilst on p 181 we are told that the surgeon should never operate for adenoids if there are symptoms of acute otitis media. The book contains many good practical points which are unfortunately lost owing to the casual way in which it is arranged

# Analytical Records
FROM
THE LANCET LABORATORY.

ACETOZONE
(PARKE DAVIS, AND Co 111 QUEEN VICTORIA STREET LONDON E C)

ACETOZONE possesses remarkable germicidal powers and it is said that a solution of this substance of the same germicidal efficiency as a 1 per 1000 solution of corrosive sublimate may be safely taken internally in large quantities This remarkable statement about acetozone will no doubt arrest attention It is a true chemical compound and in reality benzoyl acetyl peroxide, a crystalline substance soluble in oils, ether, chloroform, and slightly in alcohol. Its antiseptic property is no doubt due in part to the parent group of the molecule and in part to the fact that it yields peroxide of hydrogen by hydrolysis The specimen which we received consisted of acetozone mixed with an equal weight of inert absorbent powder The powder is characterised by a pungent acetous smell Acetozone has been employed in typhoid fever and in other diseases due to bacteria or the organisms of fermentation and in which it is possible to bring the action of the antiseptic to bear upon the infected area. We found that acetozone powder left in contact with water gradually develops free peroxide of hydrogen and a smell resembling ozone may be observed. Messrs Parke, Davis, and Co own that further clinical experience is required to establish the exact value of acetozone and they express themselves willing to furnish qualified medical men, who can conveniently undertake the work, with specimens of this substance for the purposes of investigation It certainly claims a trial.

HOPOGAN POWDER AND TABLETS
(KIRCHHOFF AND NEIRATH, BERLIN, N AM KUPFERGRABEN 6)

In the letter from our New York correspondent, published in THE LANCET of July 26th, 1902, p 252, appeared a note upon a new preparation termed Hopogan or Biogen, which in reality is pure dioxide of magnesium which appears to have been prepared in a pure state quite recently for the first time. We have received specimens of this substance as prepared for medical administration The powder practically contains pure magnesium dioxide and is free from metallic impurities or alkalies It is not soluble in water but on the addition of hydrochloric acid some oxygen is evolved and peroxide of hydrogen and chloride of magnesium are found in the solution Tablets are prepared containing eight grains of the pure dioxide in milk sugar It is proposed to administer magnesium dioxide in cases of deficient oxidation of the blood and already some encouraging results are stated to have been obtained. The preparation, we think, should receive some attention, as affording a method of administering oxygen internally which has not been convenient before, since other peroxides are unsuitable for the purpose

FERROLEUM
(THE FERROLEUM Co , 86 CLERKENWELL ROAD LONDON, E C)

This is a successful combination of the well-known valuable remedies cod liver oil, iron, and phosphorus The formula is no secret and our analysis showed the presence and amount of constituents as described. The following were the results moisture, 47 81 per cent., oil with traces of phosphorus, 40 00 per cent , pure glycerine, 10 76 per cent , phosphate of iron, &c , 1 43 per cent. The iron is present in a suitable form, being readily absorbed whilst not giving rise to the disagreeable effects of ordinary iron salts The emulsion though tasting of cod liver oil is less disagreeable to take than raw non emulsified oil The preparation is a good one and of distinct therapeutic value having regard to its constituents and the particular form in which they are presented. The association of an easily assimilable oil in a fine state of division with a phosphatic salt of iron which does not disturb the digestive functions and which is easily tolerated determines the success of the preparation as a food and tonic in wasting diseases

STERULES
(WILLIAM MARTINDALE AND Co , 10 NEW CAVENDISH STREET, LONDON W)

The convenience of "sterules" is obvious They simply consist of sterile capsules of eye drops "Sterules" are thus prepared containing solutions of definite strength of the salts of atropine, cocaine, euphthalmine, homatropine, physostigmine, and pilocarpine This method of preserving eye drops is excellent.

ODOL
(ODOL CHEMICAL WORKS 26 SOUTHWARK BRIDGE ROAD, LONDON, S E)

We called attention in THE LANCET of July 26th, p 224, to the peculiar antiseptic properties of odol which render it useful for the purposes of a mouth wash It was then pointed out that it contained a definite oily compound of phenol and salicylic acid It is important to note that this compound is not the crystalline derivative salol, but the curious yellow oil present, though not itself antiseptic, splits up into phenol and salicylic acid when in contact with the mucous membrane or the saliva. It is this property which makes odol a very efficient antiseptic for the mouth In discussing analytically the previous sample sent to us we noted a flavour of peppermint. In the sample since received this flavour is not so much in evidence, that of oil of roses, which to many persons is more agreeable, being substituted

(1) BEEF TEA AND (2) CHICKEN BROTH
(FRANCO-AMERICAN FOOD Co , JERSEY CITY HEIGHTS, N J)

Both these preparations are of a very limited nutrient value since the total amount of solid matter in the beef tea was found to be only 2·75 per cent and in the chicken soup 3 22 per cent The amount of proteid in the former was quite small, while the latter contained a slightly greater proportion Taking into regard, however, the total solid constituents of the preparations, both of which are clear fluids, we can admit of no special food value attaching to them.

VARIOUS BORDEAUX WINES
(AGENCY: MACMINN, RICHARDSON AND Co 11 HART STREET MARK LANE, LONDON, E C)

The wines now described with our analyses appended are stated to come from "the celebrated Vergniaud Cellars in

Bordeaux." They are offered at reasonable prices from 18s per dozen upwards. The following are the results of our examination of the various samples submitted to us and our observations based on these results. Claret V D 0 (60s) alcohol, by weight 10 85 per cent by volume 13 43 per cent. equal to proof spirit 23 54 per cent. , extractives 2 44 per cent , mineral matter 0 26 per cent. sugar 0 16 per cent. , volatile acids reckoned as acetic acid, 0 108 per cent. , and fixed acids equal to tartaric acid 0 262 per cent. This wine is described as Chateau Mouton Rothschild and its excellent character is in keeping with the renown of this celebrated 'chateau." It is an elegant wine, delicate, free from excessive acidity containing a minimum of sugar Claret V D 1 (44s) alcohol, by weight 10 85 per cent. by volume 13 43 per cent equal to proof spirit 23 54 per cent. , extractives, 2 28 per cent mineral matter 0 24 per cent. sugar 0 14 per cent volatile acids reckoned as acetic acid, 0 12 per cent. and fixed acids reckoned as tartaric acid 0 22 per cent. This wine is from the Chateau Montrose and its analysis is in some respects similar to the previous wine it is sound and pleasing Claret V D 2 (36s.) alcohol by weight 10 08 per cent. by volume 12 49 per cent. equal to proof spirit 21 89 per cent. extractives, 2 34 per cent. mineral matter 0 24 per cent. sugar 0 16 per cent. volatile acid reckoned as acetic acid 0 102 per cent. and fixed acids reckoned as tartaric acid 0 262 per cent. This wine is described as Chateau Talbot" and as will be seen is slightly less alcoholic than the previous wines. It possesses excellent bouquet and flavour and shows a minimum degree of acidity and a negligible amount of sugar Claret V D 3 (28s) alcohol by weight 10 85 per cent. by volume 13 43 per cent. equal to proof spirit 23 54 per cent. extractives 2 47 per cent. mineral matter 0 24 per cent , sugar 0 16 per cent. volatile acids reckoned as acetic acid, 0·098 per cent. and fixed acid reckoned as tartaric acid 0 225 per cent. This is Larose" claret, an agreeably light and practically non acid wine. Claret V D 4 (23s) alcohol, by weight 12 38 per cent., by volume 15 30 per cent. equal to proof spirit 26 83 per cent extractives, 2 71 per cent., mineral matter 0 27 per cent. sugar 0·17 per cent., volatile acids reckoned as acetic acid, 0 072 per cent., and fixed acids reckoned as tartaric acid 0 285 per cent This is St Julien (Adet) a somewhat heavier wine than those previously described but sound and non acid and practically free from sugar with a *satisfactory flavour* Claret V D 5 (18s) alcohol by weight 10 85 per cent. by volume 13 43 per cent. equal to proof spirit 23 54 per cent extractives 2 67 per cent mineral matter 0 27 per cent. sugar 0 21 per cent. volatile acids reckoned as acetic acid 0 078 per cent. and fixed acid reckoned as tartaric acid, 0 307 per cent. This is a wine from the Margaux district it is somewhat fuller in character than the others but a genuine, pleasing wine. V D Chablis (26s) alcohol by weight 10 85 per cent. by volume 13 43 per cent equal to proof spirit 23 54 per cent extractives 2 62 per cent. mineral matter 0 28 per cent sugar 1 20 per cent. volatile acids reckoned as acetic acid 0 084 per cent. and fixed acids reckoned as tartaric acid 0 42 per cent. This is a clean" wine with the well known characteristics of Burgundy (blanc) containing distinctly more sugar than the clarets while its alcoholic strength is the same. V D Volnay (36s) alcohol by weight 13 15 per cent. by volume 16 42 per cent. equal to proof spirit 28 46 per cent. extractives 2 69 per cent. mineral matter 0 24 per cent. sugar 0 21 per cent. volatile acids reckoned as acetic acid 0 03 per cent. and fixed acids reckoned as tartaric acid 0 20 per cent This is a quite sound Burgundy with practically no acidity a somewhat robust" and palatable wine. V D Pommard (28s.) alcohol, by weight 12 38 per cent. by volume 15 30 per cent. equal to proof spirit 26 82 per cent. extractives 2 74 per cent. , mineral matter 0 20 per cent. sugar 0 23 per cent. volatile acids reckoned as acetic acid 0 102 per cent., and fixed acids calculated as tartaric acid 0 262 per cent. A well known wine with a "vigorous" composition, soft to the palate, and in sound condition V D Beaune (23s) alcohol, by weight 11 62 per cent., by volume 14 37 per cent. equal to proof spirit 25 18 per cent. extractives, 2 90 per cent. mineral matter, 0 25 per cent , sugar, 0 30 per cent., volatile acids 0 102 per cent. and fixed acids, 0 307 per cent. This is a somewhat full bodied wine, but of comparatively low alcoholic strength, possessing the flavour of a sound Burgundy V D 0 Chateau Yquem (60s.) alcohol, by weight 11 62 per cent. by volume 14 37 per cent. equal to proof spirit 25 18 per cent. extractives 4 68 per cent. mineral matter 0 20 per cent. , sugar 2 90 per cent. acetic acid, 0 048 per cent. and tartaric acid, 0 51 per cent. This is an excellent Sauterne evidently with some age. It is practically free from acidity and contains an appreciable amount of sugar the taste being somewhat sweet The flavour is full bodied and excellent V D 2. Haut Sauterne (36s.) alcohol by weight 13 15 per cent. by volume 16 24 per cent. equal to proof spirit 28 46 per cent. extractives 3 59 per cent. mineral matter 0 28 per cent. sugar 1 66 per cent , acetic acid 0 18 per cent. and tartaric acid, 0·337 per cent. This is a very agreeable wine of higher alcoholic strength than the last and with a small amount of sugar The wine was in good condition. We are not aware of the respective vintages of the above wines but they are evidently selected from good years. They were all in fine condition being characterised by a practical absence of acidity and a minimum of sugar and alcohol. We believe them to be pure natural wines and it is satisfactory to note that wines of such a class can be offered at moderate prices. In this interesting series of analyses of typical red and white wines it is interesting to observe that throughout the degree of acidity of the white wines was slightly in excess of the red wines a result which is opposed to the views of some people. Moreover the white wines as a rule, contained more sugar than the red wines though in no case was the amount excessive. These results as regards Bordeaux white and red wines agree with those published by THE LANCET Commission on the Medical Use of Wines in THE LANCET of 1880 [1] and our Commissioners were led to point out the advantages of clarets over white wines in regard to acidity and sugary contents, especially for those *suffering from diabetes or gout.*

V O BRANDY

(LUCIEN FOUCAULD AND CO., COGNAC. LONDON: E. W LAWTON AND CO. HOPETOUN HOUSE, LLOYDS AVENUE, CRUTCHED FRIARS, LONDON E C)

As the following analysis shows this spirit presents characteristics typical of genuine matured brandy produced in the Cognac district alcohol by weight 44 18 per cent. by volume 51 82 per cent. equal to proof spirit 90 81 per cent. extractives 1 47 per cent. mineral matter 0 03 per cent. , total acidity reckoned as acetic acid, 0 06 per cent. alcohol in ethers, 0 21 gramme per litre aldehyde 0·020 gramme per litre and furfural, 0 005 gramme per litre. The taste is agreeably smooth though somewhat sweet, a small proportion of burnt sugar being detected in the extract. We are of opinion that this is a genuine matured Cognac brandy

CORONATIA SOAP

(MESSRS. COOK AND CO., EAST LONDON SOAP WORKS BOW LONDON E)

We found this to be a good bland soap free from irritants and alkaline excess A feature of the soap is that though scented it imparts only a suspicion of perfume to the skin.

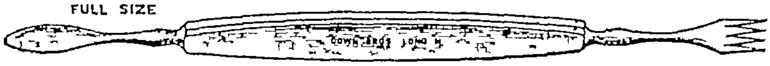
New Inventions.

A NEW VACCINATOR

I WISH to bring before the notice of the profession a vaccinator which I have had made As shown in the engraving it has a fork at one end, while at the other end there is a spatula. The scarification can be performed more quickly with this vaccinator than with a single bladed instrument, as four parallel scratches are made at a time It can easily be sterilised by boiling as it consists entirely of steel and is all in one piece It has been made for me by Messrs Down Bros, of 21, St Thomas's street, London, S E

FULL SIZE

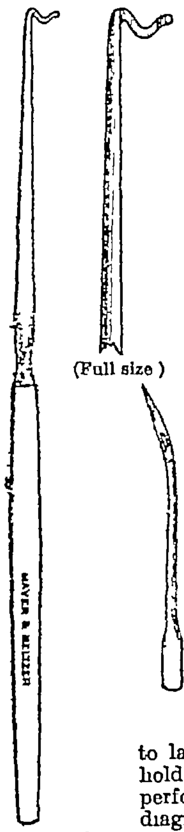


L. O S BROUGHTON, L R.C P & S Edin,
Public Vaccinator, Oldbury No 1 District
West Bromwich Union

PERITONEAL SUTURE-CATCHER AND ADJUSTER, WITH A DESCRIPTION OF THE METHOD OF SUTURE WHICH IT FACILITATES

THE purpose of this instrument (Fig 1) is to facilitate suturing (with needles having eyes at the point, as in Figs 2 and 3) in places otherwise inaccessible, where there is no room to carry an ordinary needle in and out, and where even transverse suturing with a needle having the eye at the point and mounted in a holder in the usual way is difficult to carry out—e g, a perforated gastric ulcer at or near the cardiac end of the lesser curvature and situated consequently high up under cover of the liver and the ribs

FIG 1



(Full size)

FIG 2

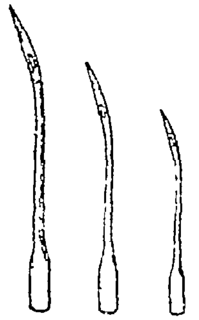


FIG 3

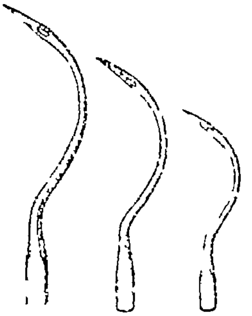

Needles (full size)

Figs 4, 5, and 6 represent such a perforation which occurred in my own practice On attempting to pass a suture transversely the point of the needle was buried in the under surface of the liver almost as soon as it emerged from the surface of the stomach. It was found possible to lay a suture only in the line of the needle holder This was done first on one side of the perforation, then on the other, as shown in the diagram, a device which has no doubt been repeatedly adopted by other surgeons in similar circumstances Considerable difficulty was, however, experienced in disengaging the suture from the needle with fine forceps and other instruments at hand which led subsequently to my designing the little instrument shown in Fig 1 Its use in this method of suturing will be seen at a glance The flattened point (*a*) at right angles to the shaft lifts one loop of the suture off the needle (Fig 4) The hook with the concavity (*b*) upwards enables the loop to be held *in situ* while the needle is withdrawn (Fig 5), while the hook with the concavity towards the handle (*c*) draws the free end of the suture through (Fig 6) It will be noticed that each suture placed as indicated is practically equivalent when tightened up to two ordinary Lembert's sutures Furthermore, it has less tendency to cut out, inasmuch as when tightened the traction strain is equal at both ends of each puncture channel instead of being all thrown upon the outer extremity of the channel, as is the case when the needle is introduced transversely

FIG 4

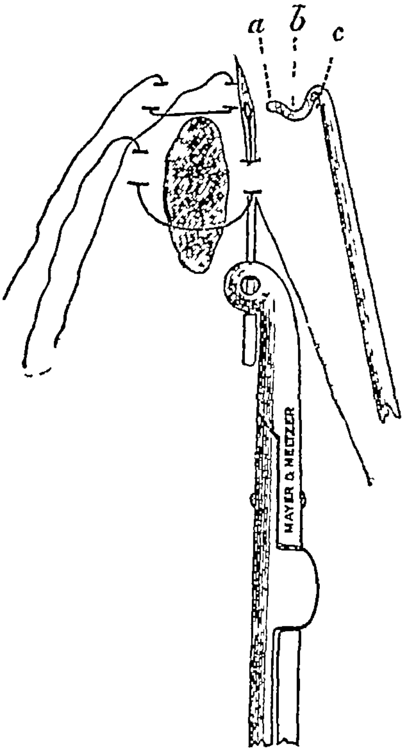

FIG 5

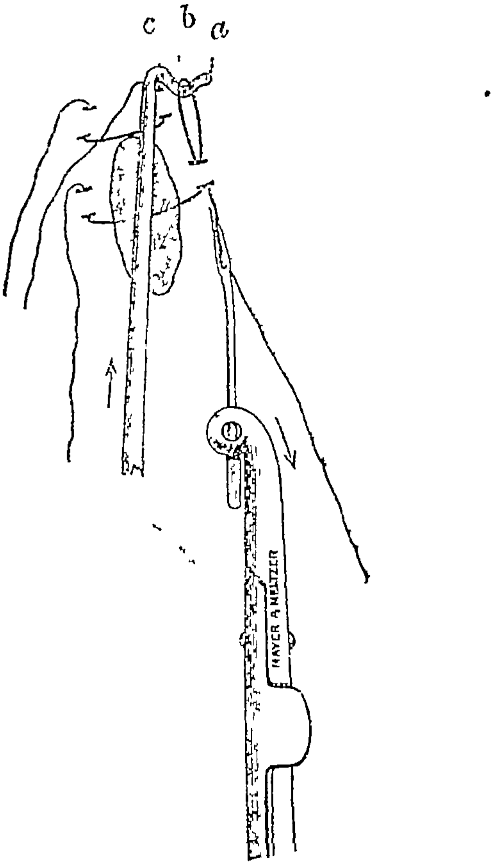
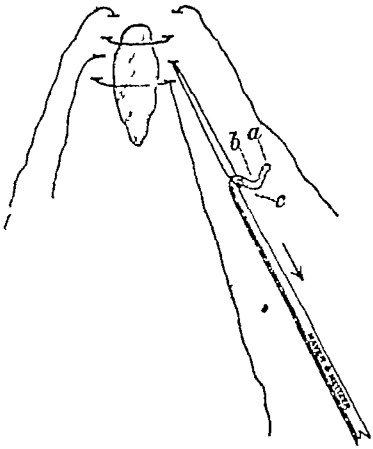


The needles are curved on the flat with the eyes at the points and are made in two curves and three lengths as shown in Figs 2 and 3 The only special point about them is that the butt is flattened either laterally, as shown in the illustration, or antero posteriorly They can thus be readily and firmly adjusted to and set at any angle in, the needle-holder.

Fig 6

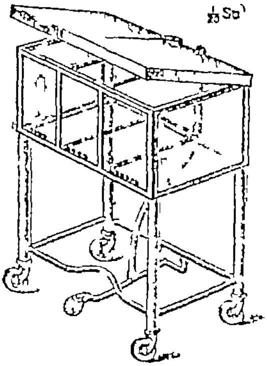


The instrument and needles were made by Messrs Mayer and Meltzer of Great Portland street, London, W

W F Brook F R C S. Eng
Senior Surgeon to the Swansea General Hospital.

A NEW ASEPTIC CABINET

The illustration shows a new form of aseptic cabinet for dressings made for use in the Sussex County Hospital at the suggestion of Mr O N Chadborn. The cabinet is made of glass and metal throughout and is white enamelled. Being fitted on ball bearing castors it runs easily and noiselessly up and down the ward, and possesses the advantage that the nurse can dress a case single-handed as after the hands have been made aseptic the lid is opened by the foot by means of the lever rendering it unnecessary to touch the cabinet with the hands Messrs. Down Bros. of 21 St Thomas's-street, London, S.E., are the makers.



Accident to a Medical Practitioner.—On August 25th Dr Mary Helen Cruikshank of Portland place Reading while driving home in a light cart from the railway station was thrown out with great violence on the roadway where she lay unconscious. Dr William J Maurice and Dr Martha F Armitage who were quickly in attendance found that she had sustained concussion of the brain Consciousness was regained in the course of the day and the subsequent history of the case has fortunately shown a gradual improvement.

Looking Back.

FROM

THE LANCET, *SATURDAY, SEPT 4*, 1824

To the Editor of The Lancet

Sir,—It was with much pleasure that I read two letters in your publication of the 17th and 31st of the last month relative to the inattention shown by the surgeons of St. Thomas's Hospital to the students attending there: inattention so long continued and so frequently the subject of animadversion and dissatisfaction among the students themselves, that I am surprised that public notice has not been taken of it at an earlier period.

The fame which St. Thomas's and Guy's Hospitals have acquired is not unknown to the officers of these establishments, and to this circumstance it may be feared is to be attributed in some degree, the neglect complained of and which has now become so glaringly manifest.

Be this as it may every consideration demands that it be rectified as speedily as possible and that conduct so unworthy of surgeons and teachers be superseded by a behaviour more congenial and better adapted to advance the improvement of the pupil The interest of the parent calls loudly for this who is at an enormous expense in enabling his son to prosecute his studies there, and is blindly led to believe, that every facility is afforded of doing it with advantage the interest of the son, who gives his attendance for the purpose of gaining information, but which he has the mortification of finding when too late, to be extremely superficial and partial, and lastly the interest of the public, on whom, in after time, this flimsy knowledge is to make its dangerous experiments.

What are the opportunities which the student possesses there of becoming acquainted with the character and treatment of disease? why I know of none, and I speak candidly except it be the privilege of running up and down, from ward to ward, after the surgeon, and hearing or rather seeing him whisper to one or two gentlemen at his elbow who are generally his own dressers or acquaintances, and who rudely push their way through the other students to get to that situation. The majority of the pupils may look and stare, as long as they please, but all to no purpose If it be endeavoured to make up for this by having recourse to the Hospital books, in order as one of your correspondents expresses it, to catch what he can," he is still disappointed for there he does not find the slightest clue to direct him in forming an opinion as to the nature of any cases on which he wishes for information, no name of the disease and no report of any kind Prescriptions only meet the eye, and these are in writing so obscure, that not unfrequently all attempts to unravel them prove unavailing One is apt to think, on looking at them, that there was some prize at stake, for which the surgeons were contending and which was to be awarded to that competitor who wrote worst. In short, there is such mystery pervading the whole that it is impossible for a student to reap any benefit from attending that institution

When Sir Astley Cooper goes round the wards of Guy's Hospital he directs the attention of the pupils to any case of interest that presents itself to his notice and in a voice so audible as to be distinctly heard by every one of them. Thus he fulfils the engagement into which he enters the moment the fee of the student is received This honourable conduct on his part is fully appreciated, and hence it is, as well as from his eminent abilities that his visits are so much desired and longed for But, Mr Editor is not the same duty imperative on the other surgeons? Do they not receive the pupils money as well as Sir A. Cooper? they do and therefore are equally bound to make a suitable return, which they cannot be said to have hitherto done If any thing more than another be calculated to act as a reproof to these gentlemen it is the open, fair and honourable behaviour of Sir A. Cooper.

You have done much Mr Editor towards putting down some of the abuses connected with this hospital and I trust you will yet do more. There is a wide field before you and your labours can scarcely be more advantageously or fitly employed than in clearing it of its weeds.—Go on in the work, and you shall earn the gratitude of every impartial and honest man and greatly befriend,

Sir Your obedient Servant,

R.

LONDON SATURDAY, SEPTEMBER 6, 1902

The Cremation Act

AN Act of Parliament to be known as the Cremation Act, 1902, and to be applied to England, Wales, and Scotland, but not to Ireland, received the royal assent on July 22nd last and will come into force on April 1st, 1903, in order to enable public authorities charged with the duty of providing for the burial of human remains to provide for the disposal of them by burning The text of the Act will be found at p 700 Public opinion has to a great extent become accustomed to this method of dealing with the dead since the outcry which greeted the sporadic and experimental burning of bodies in the early "eighties." Many have almost forgotten that at that time the legality of cremation was questioned even by the legal advisers of the Government, and that the projected construction of a properly equipped crematorium by those interested in the movement was abandoned owing to the attitude of the Home Office This state of things was only put an end to when Mr Justice STEPHEN, in charging the grand jury called on to consider the indictment against a man named PRICE in Wales (R. *v* PRICE, 12, Q B D, 247), made a careful and exhaustive survey of the laws and customs relating to the treatment of human remains so far as these were relevant to the subject before him, and drew the conclusion therefrom that the person who burnt a dead body instead of burying it did not commit a criminal act unless he did it in such a manner as to amount to a public nuisance at common law At the same time he added, with particular reference to the case before him, although to burn a dead body decently and inoffensively is not criminal it is obvious that if it is done in such a manner as to be offensive to others it is a nuisance of an aggravated kind Sir FITZJAMES STEPHEN went into the matter with his usual thoroughness and courage, and no one, so far as we are aware, has ever questioned the authority of his opinion, but the new statute gives formal legal sanction to cremation by providing that "the powers of a burial authority to provide and maintain burial grounds or cemeteries, or anything essential, ancillary, or incidental thereto, shall be deemed to extend to and include the provision and maintenance of crematoria." The plans and sites of these crematoria are to be subject to the approval of the Local Government Board, restrictions are imposed with regard to their propinquity to dwelling houses and to public highways, and the Home Secretary, who will have to be satisfied that they are properly constructed and equipped, will make regulations for their conduct, maintenance, and inspection.

A section in the Act provides not only against breaches of its regulations, but imposes heavy penalties with a view to the mitigation of those dangers which, in the present state of the law as to death certification, must in some degree be increased by the possibility of quickly and completely destroying human remains Under this section every person who shall wilfully make any false declaration or representation, or sign or utter any false certificate with a view to procure cremation of a body, shall be liable to a sentence of two years' hard labour, and every person who shall procure or attempt to procure the same object with intent to conceal the commission, or to impede the prosecution, of any offence shall be liable to penal servitude for five years At the same time nothing in the Act is to interfere with the jurisdiction of coroners or to sanction the creation of a nuisance, and the scruples of those who are opposed to cremation from a religious point of view are protected by the provision that the incumbent of a parish shall not be under any obligation to perform a funeral service before, at, or after the cremation of the remains of his parishioners, but power is given to call in other clergymen on such occasions if it be desired

We have sketched above the outline of a statute which will no doubt in process of time be usefully applied in those districts where lack of space and overcrowding of the living render the safe and economical disposal of the dead a matter of difficulty and where the introduction of cremation by private enterprise would not be likely to command success That such a measure should have been passed shows the gradual development of public feeling in the direction of sanitary improvement, while the delay that has attended it illustrates the necessity for the gradual rather than rapid education of public opinion where matters more or less of sentiment are involved. The medical profession has always taken a keen interest in all questions affecting the safe disposal of human remains, and with the introduction of cremation as a means to this end the names of Sir HENRY THOMPSON and Sir T SPENCER WELLS (to mention no others) will always be indissolubly connected. Those of the pioneers of the movement who survive will, no doubt, view the new enactment with satisfaction and will do all they can to encourage its application where its adoption is likely to be useful and conducive to the public health

◆

Cancer Research.

THE Cancer Research Fund has now reached a pecuniary position which enables preliminary working arrangements to be taken into consideration by the Executive Committee, and on the decisions of the Executive Committee as to the lines on which the fund is to be administered depends very largely the degree of success which will attend the project—a project which has been honoured by the presidency of the PRINCE OF WALES and supported in liberal measure by money contributions from the general public. It is understood that the provisional scheme for the working of the fund which was considered by the Royal Colleges of Physicians of London and Surgeons of England suggested (1) the starting and equipment of special laboratories to be devoted entirely to research work bearing on the subject of cancer, (2) the encouragement of research work in connexion with cancer within the United Kingdom or in the British dominions beyond the seas,

(3) assistance in the development of cancer research work in various hospitals and institutions, and (4) the provision of means for systematic investigation generally into the causes prevention and treatment of cancer. A meeting of the Executive Committee has now been held and as our readers are aware it has been decided that a General Superintendent of Cancer Investigation shall be appointed to carry out the work much in accordance with this provisional scheme. We may with advantage briefly recapitulate what has been done in this country and abroad in the general direction of systematic research into the cause of cancer before we consider the special task that lies before the Executive Committee of the Cancer Research Fund.

The Cancer Research Laboratories of the Middlesex Hospital were the first special laboratories to be founded in this country for the study of malignant disease. In 1899 the staff of the hospital drew up a scheme which included the foundation of the laboratories, the constitution of a Cancer Investigation Committee, and the appointment of a special staff for carrying out the work. The Cancer Research Laboratories were opened for work in the beginning of 1900 and the first volume of reports is just announced. The next organisation founded to deal specially with cancer research was the German Comité für Krebsforschung which was constituted in 1900 with Professor VON LEYDEN as President and Professor GEORGE MEYER as general secretary. The Comité includes two vice-presidents, seven honorary members nine foreign members, and 62 German members. The foreign members include three representatives from this country two from France, and one each from Egypt, the United States Japan and Russia. The German members include all those who in that country have been specially identified with the investigation of malignant disease. The Comité occupies itself mainly as an administrative body to encourage and to assist financially individual research work in immediate connexion with the causation of cancer to collect and to tabulate information bearing on the subject, and to further generally the advancement of scientific knowledge in connexion with cancer. The maintenance of laboratories of its own does not enter into the working scheme. The Comité is so far recognised by the State that its meetings are held at the offices of the Ministerium des Inneren and it receives an annual grant of 5000 marks from the Government. The first volume of *Verhandlung des Comités für Krebsforschung* (heft I. 1900–1902) has recently been published in Berlin. Other special cancer research laboratories have been founded on similar lines to those of the Middlesex Hospital. In Germany there are two under the direction of Professor VON LEYDEN and Professor EHRLICH respectively. The former laboratory is worked in connexion with Professor VON LEYDEN'S special cancer ward at the Charité Hospital in Berlin which contains 34 beds and is supported by the State at an annual charge of 53,000 marks. Professor EHRLICH'S cancer laboratory is in Frankfort and is supported by private contributions. In the United States the first cancer research laboratories were those at Buffalo which are now under the Department of Health of the State of New York and which have been materially assisted by private benevolence. A legacy from CAROLINE BREWER CROFT enabled the Cancer Committee to the Surgical Department of the Medical School of Harvard University to organise a commission of pathologists to carry on special research work in connexion with cancer in the pathological laboratories of the university. This commission issued a short preliminary report in October 1900 and a fuller one in February of this year. In addition to these purely scientific bodies cancer leagues and societies constituted on semi popular lines have come into existence with the object of educating the public generally as to the importance of cancer research. Of these schemes some are less wise than others, but all have a good object and should therefore be regarded by medical men with broad sympathy.

It will thus be seen that work which is already in progress indicates with some clearness certain of the lines on which the Executive Committee of the Cancer Research Fund may proceed. It may support research work in cancer in pathological laboratories already existing in the London and provincial medical schools, from which laboratories the pathological work on which the scientific reputation of this country depends has hitherto gone out. It may in addition, maintain a central bureau for the collection and tabulation of the results of laboratory research work and of other investigations bearing on the causation of malignant disease, it may establish new laboratories apart from the medical schools and carry them on under its own supervision. The Executive Committee will proceed early in October to appoint a General Superintendent of Cancer Investigation, and it will be seen that the duties of the office, detailed in our advertisement columns on August 9th foreshadow the direction in which a start will be made. These duties include (1) the general direction of laboratory investigation (2) the supervision of workers appointed by or receiving grants from the Committee (3) the collection of statistical, dietetic, topographical, and other information, (4) the organisation of a system of correspondence with colonial Indian and foreign laboratories and workers and (5) attendance at the meetings of the Executive Committee or any committees appointed by them for special purposes relating to the investigation. With regard to the establishment of new laboratories, it is to be hoped in the interests of British pathology that no hasty decision will be arrived at. The General Superintendent may also be appointed Director of the Central Laboratory but unless this laboratory be in connexion with a general hospital the work there should be rather critical and generally supervisory. The results obtained up to the present time by pathological laboratories endowed for research work independently of connexion with sources from which to draw their supplies of necessary material, have not been such as to encourage the endowment of others of a similar kind. And the institution of new laboratories for cancer research work, unless such laboratories were intimately connected with general hospitals from which an adequate supply of material for investigation could be readily obtained would be a mistake. The opinion of those who from practical experience are familiar with the actual necessities of laboratory research work is we believe unanimous on this point. What has been done at the Middlesex Hospital with the help of its Cancer Research Fund could be done at other of the large London hospitals if the necessary financial support from the executive committee of the Cancer Research Fund were given. At the great general hospitals of the metropolis and the large provincial towns there is, alas, a practically unlimited supply of material directly at hand. If the laboratories attached to these institutions were used there would be no necessity for the Cancer Research Fund to spend money on laboratory accommodation or on a large staff, the laboratory accommodation already available would be ample and the leading pathologists in the country could be utilised for the direction of any research work. And it may safely be said that a sum of £1000 or £1500 judiciously distributed among existing hospital laboratories would enable the committee to show better results for the expenditure of the funds entrusted to it than thrice that amount spent in maintaining laboratories where ordinary facilities for obtaining material for investigation might be wanting Nor are economy and the certainty of obtaining plenty of material whereon to work the only, or even the principal, advantages of carrying on such research in laboratories attached to general hospitals Another great advantage is that those engaged in research in connexion with cancer would have the benefit of constant contact with colleagues engaged in research work on other lines, and so there would be no danger of work being nullified by the narrow specialism which would inevitably beset workers dealing with only one form of disease and isolated from their fellows. A further argument in favour of distributing the research work over a rather wide area is that there would be less danger of the work following one groove too closely In every laboratory the trend of research work is mainly controlled by the opinions of the responsible head With regard to the causation of cancer there is at present so wide a divergence of opinion that it would be unfortunate if research work were confined to too narrow a field. By all means let there be a central bureau for the comparison and codification of results, but let the foci for gaining information be reasonably numerous and let the workers at these foci have a free hand. Their results should be brought into line by the central authority, but the directions of their labour should be left largely to themselves

The care which has been displayed in the preliminary stages by the promoters of the scheme, and the Royal support afforded to the two English Colleges in this matter, give every reason to hope that a national scheme of investigation will be drawn up in which the voice of those especially connected with pathological research work will carry due influence. One of the best informed and ablest pathologists in our country, the professor of pathology in Cambridge University, is a member of the Executive Committee This is in itself a guarantee that the real needs of the working pathologist, if his research is to have a fair chance of bearing fruit, will be clearly placed before the Executive Committee We trust that the Executive Committee will see the whole question of cancer research as the working pathologist sees it and will, in the first place, stimulate the labours of our well-established laboratories and assist processes of inquiry already commenced. Nor must it be forgotten that although the inquiry at first will be directed mainly to the pathological aspect of the question, the clinical side must also take the important position it merits The assistance of the large general hospitals will then become a necessity It would be manifestly advantageous to the progress of the investigation for the physicians, surgeons, and pathologists of the same institution to work together In this way results may be obtained which will justify the influential support which has been afforded and which will encourage the further endowment of the work

◆

The Prevention of Cruelty to Children

THE council of the National Society for the Prevention of Cruelty to Children is to be congratulated on the report of the society's progress during the year 1901-1902 Thirty seven new centres of work have been added to those already in operation, the whole number being now 877, or, with those in Scotland included, 924 The annual income has been increased by £1807 and there is a balance in hand of £231 after payment of the year's expenses There are, however, arrears of debt incurred in less prosperous years amounting to £7151. As mentioned by us in a previous issue, the society has been able, chiefly through the generosity of two of its supporters, to open new central offices The *modus operandi* of the society is explained with much clearness in this report. Its primary object is, of course, the protection of children, but it does not seek to attain this object by a blind and mechanical application of its legal powers. Nor does it even seek this desirable end alone. Recognising in cruelty something morbid and at variance with the normal domestic order it deals with it as such Accordingly, while affording protection, and if needful by extreme measures, it is not forgetful that home conditions have to be improved if the children's happiness is to be more than temporary It is, we think wisely, averse to any system of permanent removal, even from poor homes, if this can be avoided, and it therefore devotes its energies largely to the task of so reforming the manner of life in such homes as to make them at least decently habitable This ought not to be too high an ideal for attainment and it has not proved to be unattainable Even where parents have been imprisoned for their misconduct we are informed that in the vast majority of cases children have been restored to them and further supervision has revealed an alteration in the domestic life of the family and a return to natural, that is to humane, conditions Furthermore, the interest of neighbours is enlisted and a species of local public opinion in favour of fair play to the children is encouraged Thus the operations of the society may be said to be conducted in accordance with the *vis medicatrix naturæ*, and they appear to be rather appreciated than resented even by the delinquent parents themselves It is suggested in the report that if the educative principle were more freely employed in home life in relation to such other evils as the various forms of juvenile depravity the costly machinery of industrial schools and reformatories might be to a great extent dispensed with Whether, and if so how far, this arrangement is a possible one is still an open question. The suggestion that such works of social reclamation should utilise the family tie as far as possible and should, other things being equal, prefer a more natural to a more artificial method of procedure is at all events worthy of consideration.

Among other matters discussed at the annual meeting of the society was that of the protection of nurse children. It is generally understood that the existing law on this subject does not go nearly as far as is required for its full efficiency It does not cover the case of single nurse children or of children for whose maintenance a sum of £20 is paid. We confess that we have never been able to discover any reasonable justification for the exception in either case. These children obviously stand in no less need of supervision than do others of the same age entrusted to the hands of strangers for neither money nor isolation can provide a guarantee for good treatment. It is highly satisfactory to find that an amendment promoted by the society expressly aims at the abolition of this distinction which can only be regarded as a blot upon an otherwise useful Act. An objection has we understand been brought forward by a body known as the Rescue Society of London on the ground that certain women who act as nurses dislike inspection. In view of the obvious necessity for the proposed amendment we trust that no such unreasonable opposition will be suffered either to defeat its intention or to weaken its effect by qualifying concessions.

◆

The Work of the Government Laboratory

THE Government laboratory fully justifies its creation and maintenance. Time was when it was considered that apart from Customs and Excise a practical chemical laboratory could play but a small rôle in the administrative affairs of the country The report of the principal chemist upon the work of the laboratory for the year ended March 31st, 1902, abundantly shows how important it is that the Government should have its own chemical advisers and laboratories. The total number of analyses and examinations made at the laboratory in Clement's Inn Passage in the year ended last March was no less than 80 421. Of these, 64 152 were due to revenue departments and 16,269 to other departments, such as the Admiralty the Board of Trade, the Board of Agriculture, the Local Government Board the Home Office, the Post Office and the War Office, and the number of samples referred under the Sale of Food and Drugs Act was 119 As to the work of the Customs branch of the Government laboratory it has more than doubled in magnitude during the past year the actual number of samples submitted for test being 64,560 as against 34 434 in the preceding year The increase is thus about 3000 samples and is due chiefly to the imposition by the Budget of April 1901 of duties on sugar and cognate substances and on the numerous articles in the manufacture of which these substances are used. On account of this extra pressure on the resources of the laboratory the accommodation as well as the staff had to be increased. Two new laboratories were fully equipped on the lines of the Government laboratory at Clement's Inn and the staff was increased by the appointment of eight temporary chemical assistants. The work of the department was further relieved by the adoption of fixed rates of duty based on analytical data for certain articles of regular importation and fairly uniform composition as, for example condensed milk and tinned fruits. The number of analyses and examinations made in the Excise branch of the Government laboratory during the year amounted to 80 893, or 8471 more than in the preceding year In addition a considerable amount of experimental work has been done in connexion with the subject of arsenic in beer and beer materials with a view of defining the limitations of chemical analysis as to the amount of arsenic it is possible to determine and as to what may be regarded as a mischievous quantity As to tobacco, there has been a considerable increase in the number of samples examined the increase amounting to no less than 325 729 pounds, the description showing the greatest increase being cake tobacco and cigarettes. Dr THORPE remarks that the great increase in the weight of cigarettes exported shows that the practice of smoking tobacco in this form is still increasingly popular The continued demand for cake tobacco was due to the war in South Africa. Some samples were found to contain liquorice glycerine or sugar One instance of fraud is worth mentioning Certain persons were discovered manufacturing an imitation tobacco which was found to consist of pinewood so shredded and stained as to resemble the tobacco used for making cigarettes. The full penalty of £200 was imposed. In connexion with other Government departments the number of samples examined was 6622, more than a third of them coming from the Board of Agriculture a fifth from the Local Government Board and about a fifth from the War Office.

During the year no imported sample of butter has been reported as adulterated with foreign fat while in the previous year there were 15 adulterated butters Boric acid preservative was present in all the samples of butter from South America, in 96 per cent. of those from Belgium in 90 per cent. from Australia, in 88 per cent of the French samples, in 77 per cent. of those from New Zealand, in 50 per cent. from Holland and in 42 per cent. from the United States. Only 1 per cent. of Danish, 4 per cent. of Norwegian 6 per cent. of Russian 9 per cent. of Canadian and 15 per cent. of the German samples contained this preservative. On the decision being made by the First Commissioner of Works that analyses should be conducted of the air in the House of Commons and that of the inlets Dr THORPE arranged an investigation which was supplemented by a bacteriological examination. Accordingly when the House had adjourned for dinner on March 13th samples of air were taken at the Speaker's table and from the Members' gallery and the mixing chamber which supplies the fresh air As a result it was found that the proportion of carbon dioxide present in the air of the debating chamber was not appreciably greater than is usually found in the air of rooms with several persons present, and though as was to be expected, the number of organisms in the air of the lower part of the House was greater than in the air of the mixing chamber yet in the Members' gallery which is beyond the sphere of dust raised by the movement of persons there was no such increase of organisms, and there was further a general absence of any organisms that could be identified as pathogenic or in any degree prejudicial to health. The work on fritts and leadless glazes has been continued, though not to the extent of previous years owing to the conclusion having been arrived at in the arbitration on the matter that a considerable diminution in the number of cases of plumbism had been brought about owing to the improved working conditions imposed by the Home Office. It is satisfactory to report that the leadless glazed articles supplied to the public departments have proved to be substantially free from lead. With regard to samples referred to the Government laboratory by magistrates under the Sale of Food and Drugs Act, 119 have been examined, which means an increase of 41 samples over last year owing to the greater number of samples of butter and milk. The proportion of cases in which the Government results led to conclusions differing from those of the public analyst was 21 per cent., as against 20 8 per cent. for the previous year The chief disagreements arose out of samples of milk and butter, while as regards four samples of soap liniment said to have been prepared with methylated spirit instead of rectified spirit, as required by the British Pharmacopœia, in only one of these cases could the certificate of the public analyst be upheld. While upon this subject we may note that according to a statement furnished to the Home Office by the Local Government Board, out of a total of 2673 fines imposed by magistrates under the Sale of Food and Drugs Act during one year 764 were of 10*s* or less, 193 of less than 5*s*, and 118 of 1*s* or less For years we have urged that the fines have been utterly inadequate and so absurdly small as practically to defeat the real object of the Act—viz , the protection of the people against fraudulent practices and against injurious additions in regard to food. It is time that this silly state of things should be remedied and by no uncertain method.

Annotations.

"Ne quid nimis"

KING EDWARD'S HOSPITAL FUND FOR LONDON

THE Honorary Secretary of King Edward s Hospital Fund for London has forwarded to us the following statement with a request for its publication His Royal Highness the President and the Executive Committee of King Edward's Hospital Fund for London have great pleasure in announcing that they have received from Lord Mount-Stephen and Lord Strathcona an endowment to King Edward's Hospital Fund for London, producing at present £16,000 per annum, and likely to increase in value. This most munificent gift will go far to complete the scheme inaugurated by His Majesty the King when Prince of Wales in 1897 to free the London hospitals from debt. It is earnestly hoped by all connected with the Fund that the sum still required to secure £100,000 per annum, the amount stated in the original appeal to be necessary to carry out the work of the Fund, may be obtained during this the first year of His Royal Highness s Presidency The munificence of these two Canadian noblemen in this year of Empire is one more token that the London hospitals are in no sense local charities but Imperial houses of healing Their patients are indeed drawn from an even wider sphere than that ruled over by His Majesty King Edward VII That their income is in no way commensurate with the work which they have to do has been for many years only too evident, but the scheme set on foot by the King when Prince of Wales in 1897 bids fair to set these institutions on a sound financial footing Not only have the inhabitants of these islands given of their wealth and of their poverty but the great Indian princes and now the Canadian merchant princes have stretched out a helping hand to the sick and needy That the full sum to be made up will soon be obtained is the wish of all and we congratulate the authorities of the Fund upon being within measurable distance of this end

IS THE PRACTICAL WORKING OF OUR RAILWAYS EFFICIENTLY SUPERVISED?

THAT small defects, by easily escaping ordinary observation, may lead to very grave issues has been very apparent recently in connexion with the working of our great railway systems Apart from a flaw in the rolling stock itself the possibilities of a derangement in the rails are countless Every linear foot along miles and miles of a railway may become a source of danger, perhaps by reason of subsidence, by a crack in the steel, or by the loosening of a chair or pin Experience shows, at any rate, that the derailment of trains does not always find a clear explanation, yet it is, perhaps, in modern times the most fertile source of accident In these circumstances the question naturally arises, Is the permanent way kept under constant and efficient supervision? Recent occurrences would tend strongly to show that it is not and a few instances may be cited supporting this conclusion. Not long ago the South Eastern Railway quite suddenly announced the interruption of their main line traffic owing to a grave defect which had appeared in the Grove Park tunnel near Chislehurst. It was stated that a platelayer walking through this tunnel discovered very distinct evidences of the brick work giving way Is it a platelayer's duty to report upon the masonic condition of a tunnel? If so, is he to be regarded as a competent person for the purpose? According to reports it was by sheer accident that the platelayer remarked the defect We now know that the defect was serious enough to lead the authorities at very great inconvenience to themselves suddenly to close the main line. It may be concluded, therefore that the state of the tunnel was perilously close to the possibility of disaster Was the condition of the tunnel known before the platelayer discovered it? If so, why was not the traffic diverted long before? if not, what system of supervision is adopted which failed to discover it? Again, a few weeks ago the Flushing boat express met with an extraordinary accident on the point of leaving London The train suddenly "jumped" the rails and it could only have been by a miraculous series of events that an appalling disaster was averted There were 200 people in the train who, needless to say, experienced considerable shock. Luckily, the express was travelling on rails in the centre of the track and for some most extraordinary reason several of the carriages took to the rails again by the intervention of diamond points As it was the permanent way was ploughed up and great damage was done Was this due to a defect in the rails? and if so why was it not made out? Yet again on the Great Eastern suburban line not long ago a very serious accident occurred to a very crowded train by which many persons were injured owing to the snapping of an axle Is this cause of accident also to be passed over as unavoidable? Numerous instances of trains leaving the metals and hurtling over embankments could be quoted from records That of a Hastings train on the Brighton line a few years ago was such a one Where is the system of supervision in such examples? In our own personal experience we remember once travelling in a railway carriage the wheels of which were locked by the brake for quite 10 miles It was anything but a pleasant experience crossing points at 30 or 40 miles an hour in a carriage with its wheels fixed. And yet if the station master at the first stopping station had not been informed of the fact the train in all probability would have been allowed to proceed On this information having been given, however, it was found advisable to detach the carriage from the train. What system of supervision was in operation in this case? We have heard, too of some alarming incidents in connexion with the "slipping" of carriages After the carriage has been slipped travelling perhaps, at a considerable speed, the brake has suddenly acted, with an effect upon the passengers little short of that of a collision In other cases the brake of the portion of the train running on may get beyond control and bring the train to an unexpected standstill with the result that the slip carriages may dash into the main portion of the train. Railway officials have been known to express this fear The slipping of carriages provided with automatic brakes is undoubtedly attended with risk and accidents have arisen on this account. Is the working of this system properly supervised? When traffic becomes disorganised or unusually congested many trains escape the tapping test which in the case of suburban trains is commonly applied to the wheels of the carriages at the terminus. Is the tapping test satisfactory? and if so would the omission to do it be likely to be attended with risk? These questions demand an answer and should receive the immediate and serious attention of the Board of Trade, for the examples which we have quoted are not calculated to set the minds of the railway travelling public at rest as to whether the supervision of railway tracks and rolling stock is conducted with that precision and frequency which in the interest of their lives are imperative

NEW CREMATORIUM AT LEICESTER

BY a special Act of Parliament the Leicester corporation has been empowered to establish a municipal crematorium and this has now been completed It has been erected at the rear of one of the chapels at the new cemetery which was opened on August 25th. In this chapel a screen will be placed across the chancel which will shut off the crematorium in the case of ordinary burials. In the centre of the chancel stands the catafalque, or bier upon which the coffin will rest during the service. Outwardly the catafalque will consist of oak panelling and delicate tracery of the same character as the screen. When the funeral ceremony takes place before cremation at the conclusion of the service the coffin will be silently moved by invisible machinery and will pass out of sight through folding doors at the head of the catafalque which will close behind it. When these doors are closed an asbestos shield will be raised and the coffin will be moved by the same machinery into the incinerating chamber The cremating apparatus is a furnace of the regenerative type designed by the late Mr Henry Simon president of the Manchester Cremation Society, and has been erected by Messrs Henry Simon Limited of Manchester It consists of three interior chambers the two lower of which are surrounded by air passages The lowest chamber contains a coke fire and the upper or incinerating one is that in which cremation takes place. The fire is lighted some hours before the apparatus is to be used and is supplied with air in the usual way By the time the apparatus is ready for use the walls of the air passages are thoroughly heated. Most of the direct air supply is then cut off and the partially consumed carbonic oxide from the coke is allowed to mix in the second chamber with the air heated by passing through the side air passages, the result of which is that the incinerating chamber is thus filled with gas of an intensely oxidising character in a state of incandescence. The degree of heat can be regulated in the most exact manner There is no smoke and little flame is visible before the body is introduced and with a coffin made in accordance with the by laws there is no smoke or noise during cremation. The process occupies from an hour to one and a half hours at the end of which time there remain only the inorganic residue of the bones. The by laws concerned with the crematorium are drawn up in most careful manner Two declarations must be filled in b separate medical men and both must be given on oath befor a justice of the peace or notary public while the corporatio may if it chooses order that a necropsy shall be mad at the cost of the party making the application for crema tion. The coffin must be made of dry oak, poplar or pin boards not more than three-quarters of an inch thick, woode pegs only being used in its construction. No pitch must b used for coating the inside but if the state of the body o the illness from which the deceased died make it desirabl a thin zinc lining may be inserted The charge for crema tion if the deceased was resident within the borough will b £2 2s for any other person £5 5s., but this charge may b partially or wholly remitted in cases of extreme poverty a the discretion of the corporation

THE SMOKE NUISANCE

ONCE again has fiction proved the pioneer of fact. Mr Gilbert's Lord Chancellor it will be remembered, applied t himself for leave to marry his own ward and addressed himself in terms which rendered it impossible for him ever to apply to himself again. However on being reminded that he was a just and kindly old gentleman he took heart and eventually obtained his own consent The Batterse borough council is not a court but on Sept. 3rd it summoned itself for committing a nuisance by emitting black smoke. The council's solicitor Mr P Caudwell appeared as a legal quick change artist in the double capacity of prosecutor and defender Before Mr Rose of the South Western police-court he charged himself with the offence and as the offender did not deny that he had committed it. He therefore as it was a first offence asked Mr Rose to grant a prohibition order to prevent its repe tition This outcome is we think, politic, for if Mr Caudwell had not been able to satisfy himself that a simple prohibition order would suffice he would probably have been fined (we trust heavily) this fine, however would have come out of the pockets of the ratepayers. Nevertheless after such an example of municipal purity of conscience we live in hopes of seeing the London School Board Cockerton-ising" its own accounts.

THREADWORMS AND APPENDICITIS

IN the *Gazette Hebdomadaire des Sciences Médicales de Bordeaux* of July 27th Professor Bégouin has published an important paper on Threadworms and Appendicitis which is of special interest in connexion with the correspondence which has recently taken place in our columns[1] He relates the following case. A woman aged 24 years was admitted to hospital with the diagnosis of recurrent appendicitis. For four or five years she had been subject to attacks of pain in the right iliac fossa which lasted for three or four days and disappeared for weeks or months. Once or twice there was a little swelling in the iliac fossa. Menstruation was normal and the general condition was good. Examination showed a slight tender tumefaction of the size of an almond below McBurney's point. The diagnosis lay between relapsing appendicitis and sclero-cystic ovaritis On opera tion the latter condition was found and the ovary was removed The vermiform appendix was free from adhesions but as it was a little more turgid than normally it also was removed. It contained 15 threadworms fragments of bread, and grains of starch Some of the threadworms were united in a bundle and formed a sort of plug There were four small superficial ulcers

[1] THE LANCET July 5th (p. 58) and 12th (p. 125) 1902.

(*exulcerations*) of the mucous membrane in the position of follicles which were turgid, and one of these follicles was surrounded by an infiltration of leucocytes Metchnikoff called attention to the relation between intestinal worms and appendicitis in the *Bulletin de l'Académie de Médecine* of March 12th, 1901 (p 301) He thinks that worms are often the cause of appendicitis and that the administration of vermifuges will prevent and cure appendicitis More recently (July 2nd) Kirmisson and Lannelongue have discussed the subject in the same publication But in all these papers the question has been the rôle of the ascaris lumbricalis and of the trichocephalus dispar; the threadworm was never found in the diseased appendix. Professor Bégouin can find only a single reference to the existence of threadworms in an excised appendix—a case recorded by Routier which is cited by Guinard in his article on appendicitis in the "Traité de Chirurgie" of Ledentu and Delbet (tome vii., p 476) Metchnikoff, like most authorities, admits that worms may cause ulceration of the mucous membrane, which may be the starting point of an infection penetrating the whole intestinal wall, and also that worms may mechanically obliterate the lumen of the appendix and favour exaltation of virulence of the microbes The latter condition evidently existed in Professor Bégouin's case.

THE RELATION OF EPILEPSY TO CRIME

AT the recent annual meeting of the American Neurological Association (June, 1902) Dr W P Spratling, medical superintendent of the Craig Colony for Epileptics, New York State, in an interesting contribution on the Relation of Epilepsy to Crime, pointed out that the epileptic "fit" in its classical form only constituted one half the picture of the disease, for the mental states consequent upon the fit were of the most varied and abnormal forms and constituted another aspect of the disease which possessed both clinical and medico legal importance Such manifestations varied from a condition of stupor or stupidity to one in which extraordinary crimes have been committed The insane epileptic of asylums had little facility for crime, partly because he was vigilantly supervised and partly because he was less potent for evil owing to his being more or less demented There were many epileptics who were not, or did not become, insane, and although the exact proportion was not easy to determine it could not be less than 15 or 20 per cent of the total. An epileptic who is sane at other times may, while in the peculiar mental condition following upon a fit, commit the most open and extraordinary crimes In this state, argues Dr Spratling, he stands forth as a curious anomaly under the law of responsibility, for with consciousness subverted or destroyed the brain may give expression and effect to impulses of a dangerous or abnormal nature without possibility of self control. In many cases the danger of epilepsy does not cease with the passing off of the convulsions and post-convulsive stupor, for there frequently follows a subconscious state, lasting from a few minutes to several days, during which the condition of the patient is best described as one of mental automatism with loss of the sense of personal identity He then acts like a mere machine, being able to go about as usual and able to take his meals and to perform sundry other commonplace actions as was his habit before the attack. And yet he is all the while absolutely ignorant of what he is about—his mind is a blank. In such a state he may do a criminal deed without premeditation or criminal intent, "as a railway engine may kill a person while running away without its driver" The same curious and interesting phenomenon of mental automatism may appear in cases of so-called psychical epilepsy, in which motor convulsions do not take place, but a state of acute frenzy and "blind" excitement occurs, lasting for a few hours or days This form of psycho epileptic frenzy is, says Dr Spratling, never momentary, as a study of over 1300 cases has convinced him that it lasts some time The most difficult medico legal problem connected with epilepsy is encountered in the purely psychical forms of epilepsy—those uncomplicated with convulsions or crude motor manifestations Here the patient may commit the most strange acts, such as wandering about without any consciousness of locality or sense of personal identity until he finds himself stranded away from home and friends, when normal consciousness eventually returns, a condition to which reference has already been made in these columns [1] It is not safe to oppose an epileptic while he is in such a state as he is apt to become combative and dangerous Thus a case is cited by Dr Spratling of a man who had a seizure of *petit mal* while in an elevated railway in New York By the time the guard reached him he was all right, but when the time came for him to leave the car some minutes later he made no move to go The guard took him by the arm to move him when the patient struck at him violently and a fight ensued which led to his being arrested and locked up When he came to his senses he was greatly mortified at being in jail, and on showing his card of epileptic seizures was permitted to go He was, says Dr Spratling, unconscious when he struck the guard and had no intent whatever of doing wrong Dr Spratling concludes by citing other cases where dangerous and even murderous attacks on persons have been committed by epileptics during the stage of mental automatism which may follow a fit and he points out the close analogy of this state to insanity

SERUM TREATMENT OF TYPHOID FEVER

IN the August number of the *Maryland Medical Journal* Dr William Royal Stokes and Dr John S Fulton of Baltimore publish a series of experiments which they have made in order to test the effect of a serum of high immunising power on cases of typhoid fever For the purpose of obtaining such a serum they injected hogs with pure virulent cultures of the typhoid bacillus, for these animals will stand the injection of the cultures without any discomfort, whereas in horses sloughs may form Bouillon cultures 48 hours old were injected into the tissues of the abdomen in increasing doses at intervals of about 10 days for a period of about five months—namely, from July 24th to Dec 31st, 1900 The amount of the first injection was 10 cubic centimetres and that of the last was 1130 cubic centimetres For the large injections the glass vessel intended for injecting salt solution was used, a foot-bellows being attached to it for the purpose of forcing the fluid into the tissues The animal was bled three times—namely, on Feb 27th, March 21st, and April 5th, 1901, one litre of blood yielding about 200 cubic centimetres of serum was drawn each time The results of 90 experiments with this serum on guinea pigs might be summarised by stating that the subcutaneous injection of the serum in doses of from $\frac{1}{600}$th to $\frac{1}{800}$th of the body weight will protect guinea pigs against four times the minimum fatal dose of intraperitoneal injection with the typhoid bacillus The injection of $\frac{1}{3000}$th to $\frac{1}{4000}$th of the serum by weight into the abdominal cavity will protect against five times the minimum fatal dose, and a dose of $\frac{1}{500}$th to $\frac{1}{800}$th of the body weight will protect against seven times the minimum fatal dose of the typhoid bacillus This serum has been used in the treatment of five patients suffering from typhoid fever, in two of whom no appreciable effect was produced upon the temperature, pulse, or other ymptoms, but three of them seemed to show some improvement under the serum treatment. The total amount of serum injected in each case was respectively 65 120 200 54 and 60 cubic centimetres. The amount of the individual injections varied from 10 to 40 cubic centimetres.

MORTALITY IN ITALY IN THE PROFESSIONS AND TRADES AND AMONG CHILDREN

FROM the official statistics dealing with the last statistical years 1898, 1899 and 1900, we gather that out of 100 males of every profession whatever dead from 20 years of age and upwards only 40 have lived longer than 70 years Taking the *media complessiva* (the average collectively) the priests and monks reach the highest figure, 57 per cent. having exceeded the 'term of the Psalmist, while the next in order are the capitalists and landed proprietors with 53 per cent. the mariners bargees, and fisher folk with 46 per cent. the medical practitioners and veterinary surgeons with 43 per cent , and the agricultural population with 43 per cent. Death is more premature among printers and lithographers of whom only 19 have attained 70 years. ' Guards, which in Italy means the police service, become septuagenarians only in the proportion of 19 per cent. miners and quarrymen in that of 21 per cent. , commission agents and domestic servants 23 per cent. , waiters in hotels and restaurants, 25 per cent. porters, 27 per cent barbers 28 per cent. coachmen and carters, 28 per cent. grooms tavern keepers, and restaurateurs 29 per cent , teachers and professors, 29 per cent butchers, drysalters, and sausage-sellers 30 per cent. and smiths, farriers, and mechanics 30 per cent. Infantile mortality is in marked diminution, thanks to the improved condition of the country sanitary and hygienic In fact, in 1900 (a year of exceptional mortality among children on account of the influenza) out of 1000 infants under one year of age 172 died, compared with 206 in 1897 The same proportion of deaths per 1000 is maintained in the case of children up to five years of age.

THE CAUSES AND TREATMENT OF VERTIGO A SYMPOSIUM

AT a recent meeting of the New York Academy of Medicine, a report of which has appeared in the New York *Medical News* of August 16th last, an important discussion was opened on the Causes and Treatment of Vertigo by Dr Charles S Fisher of New York. After referring to the description of gastric vertigo" as given by Trousseau Dr Fisher said that the term should be limited to cases marked by sudden onset, intense dizziness, and a sense of fear or disaster but not accompanied by loss of consciousness. These cardinal symptoms were nearly always associated with pain or oppression felt in the epigastrium and the attack was usually followed by a feeling of nausea. Actual gastro-intestinal disorder in the form of dyspepsia, gastric catarrh or constipation was generally but not always present. It seemed, however in the light of our present knowledge of gastric disorders that it was only when secretory gastric troubles with excess or deficiency of hydrochloric acid, were present that vertigo became a prominent morbid feature Ocular or aural troubles were sometimes found to exist in such patients if looked for with care. The subjective disturbances causing vertigo were probably aroused by nervous excitations carried from the stomach to the bulbo-spinal centres by the vagus nerve Many observers had noticed that vertigo followed the introduction of a stomach tube The term secretory gastric disturbance, as above used, said Dr Fisher should include those local disorders which permit of the formation and absorption of toxins in the alimentary tract, since the resulting toxæmia was often a determining factor in vertigo. In some of Trousseau's cases attacks of vertigo were precipitated when the patients looked at a revolving object, so that auto-suggestion would seem to play a rôle. Vertigo might be associated, said Dr Fisher with other forms of nervous disturbance in the same patient, such as agoraphobia or fear of open spaces Here however the cause of the vertigo was psychical while the agoraphobia was itself of psychical origin and not associated with the stomach. In the discussion which followed the above communication Dr Brandegee pointed out that congestive and inflammatory conditions of the Eustachian tube and tympanum were productive of vertigo the immediate cause being an increase of pressure within the labyrinth of the ear Dr Pearce Bailey said that tea coffee, and tobacco taken in excess produced vertigo, and that in some patients, both syphilitic and non syphilitic, the administration of large doses of iodide of potassium was followed by pronounced vertigo and a staggering gait. Vertigo was also an early symptom in general paralysis and coincided with commencing loss of memory It occurred also in other forms of cerebral syphilis and was often a warning signal of threatened apoplexy Professor Max Einhorn said that the gastric conditions present in cases of gastric vertigo were catarrh and secretory disturbances. The hyperacidity of nervous indigestion was curable by Vichy water or other alkaline remedy and when it disappeared the associated vertigo was also abolished. He cited cases where there was a deficiency of the stomach secretion with the result that rough particles of food coming in contact with the mucous membrane of the stomach caused a reflex vertigo If sufficient liquid was taken with the meals this trouble disappeared Dr Dench pointed out that syphilis produced labyrinthine vertigo, which, however responded well to dosage with mercury and pilocarpine—a fact which others who took part in the discussion were able to confirm. Most of the speakers also agreed that the local correction of aural and ocular troubles mitigated the attacks of vertigo

THE LOCAL GOVERNMENT BOARD AND MEDICAL WOMEN

THE Burnley board of guardians is in a state of rebellion against the Local Government Board in respect of the recent appointment of a lady as a resident medical officer at the workhouse. At the meeting of the guardians on August 21st a letter was read from the Board in which it is said that they consider that the appointment of a lady as assistant medical officer when a medical staff consists of two officers only is open to objection having regard to the fact that it is to be her duty to act as medical officer-in chief during the absence of that officer. The Board therefore requests that the matter will receive further consideration." The guardians however, were not to be turned from their purpose and one of them moved that the ' further consideration consist in the re-affirmation of the appointment. It was time they at any rate, showed," he said, that they were above the ordinary prejudices which seemed to act against the appointment of women who were, as in this case thoroughly well qualified not only by examination, but by practice." This was seconded and the motion was carried unanimously The question of the appointment of a young unmarried woman as junior medical officer to a workhouse where the senior is also young and unmarried is a difficult one when looked at from either the social or professional standpoint. There can be no difficulty in indicating one of the principal objections to such an appointment. In the absence of the male assistant medical officer his female colleague would be responsible for the medical work of the establishment and although she might be quite proficient in the use of the catheter and in the arresting of hæmorrhage most members of her sex would feel themselves placed in an embarrassing position by the admission of a man suffering from an extreme degree of retention of urine or bleeding profusely from a recent laceration of the external genitals. It is neither necessary nor desirable to elaborate this argument, but it is manifest that if the lady does not deal with such cases as part of her ordinary work it is hardly in the interest of a patient suffering in the way we have suggested that she should have to treat him in an emergency.

SURRA IN THE PHILIPPINE ISLANDS

THE existence of surra in the Philippine Islands is definitely announced and is causing considerable mortality among the transport animals and cavalry horses of the United States army of occupation, some 2000 animals having died from it during the last six months of 1901. The disease has proved almost invariably fatal and has caused some alarm owing to the possibility of its introduction into the United States. Captain Curry, M.D., reports that the carrier of surra in the Philippines is a biting fly, the *Stomoxys calcitrans*.[1] He has examined a large number of flies and mosquitoes but has found the trypanosome only in this species, in which it may remain alive for 24 hours after biting an infected animal. This fly is very abundant in and about Manila, especially in the stables and corrals, and it lays its eggs in the dung, in which the larvæ and pupæ thrive. As a prophylactic measure, all remedial agents having failed, the destruction or disinfection by lime or petroleum of animal excrement in all stables and corrals is recommended.

DURHAM COUNTY CONSUMPTION SANATORIUM

WE have received a copy of the third annual report of the Society for the Prevention and Cure of Consumption in the county of Durham. We cordially agree with the general tone of the report. We have frequently urged that it is the duty of medical men to educate their patients as to the danger of infection which may arise from the improper disposal of tuberculous sputum. The committee of the Durham Society has been adopting this principle. Addresses have been given to meetings of workmen, members of the Sunderland board of guardians, and the Coöperative Society, and letters have been sent to the various local authorities asking them to adopt preventive measures. Several authorities now offer the free disinfection of rooms vacated by consumptives and distribute leaflets showing the great danger of indiscriminate spitting, of breathing close and vitiated air, and the need for the better ventilation and lighting of cow-byres, as well as the more stringent supervision of the milk supply. It is interesting to note that voluntary notification of cases of consumption has been in force in Sunderland for a year and the medical officer of health states that 96 cases have been reported. Sunderland has a population of over 146,000, so that the number notified cannot be stated to be large. Further, the borough of Gateshead has also adopted voluntary notification, so that this measure is now in force amongst over a quarter of a million of the population in the county. We shall await with interest further intelligence of the result of this experiment. The report of the medical officer (Dr. J. Gray) as to the results of the sanatorium treatment is certainly satisfactory and we trust that the necessary funds will be forthcoming to provide more beds. Attached to the report is an article on "Consumption: Its Prevention and Cure." It is intended "for the use of sanitary authorities, boards of guardians, consumptives, and the general public." Information is given in a popular manner of the methods by which tuberculosis is spread and the means which may be adopted to diminish its dissemination.

ON THE "INTENSIVE" MERCURIAL TREATMENT OF GENERAL PARALYSIS AND TABES DORSALIS

PROFESSOR LEMOINE of Lille has contributed to the *Revue Neurologique* of July 30th last an important practical paper on the treatment of general paralysis and tabes dorsalis by the hypodermic injection of an organic salt of mercury in large doses and for prolonged periods. He refers to the view generally entertained by many physicians that general paralysis and tabes dorsalis are but little capable of improvement under the so called "intensive" form of mercurial treatment, and publishes a number of cases where the results of treatment, especially as regards general paralysis, are so strikingly beneficial as to suggest that the question requires reconsideration. 12 cases are recorded by him at some length, six being cases of general paralysis and six of tabes dorsalis submitted to treatment. Two out of the six cases of general paralysis are recorded below as typical and illustrative. Case 1. The patient was a man, aged 29 years, with a history of syphilitic infection. He had been well treated with mercury after he had contracted the disease and had married subsequently and begotten two apparently healthy children. He developed general paralysis later. On then coming under observation he was submitted to the form of mercurial treatment alluded to at the heading of this annotation. He was given daily hypodermic injections of benzoate of mercury to the extent of two centigrammes (three tenths of a grain) per dose, from Oct. 10th to Dec. 25th, 1897. The treatment was carried out uninterruptedly with the following results. Speech and memory, which had hitherto been impaired and defective, were much improved but the general mental weakness remained the same. From time to time since then, up to February, 1902, treatment was continued. The mental and physical conditions improved further and only a slight pupillary inequality remained. He had since 1897 begotten four children, all of whom appeared to be healthy. Case 2. The patient was a man, aged 27 years, of alcoholic habits, neuropathic predisposition, and impulsive temper. He had had syphilis when a youth, and some years afterwards he developed symptoms of general paralysis with grandiose delusions and megalomania. He was then admitted into an asylum and treated with daily injections of benzoate of mercury to the extent of two centigrammes (three tenths of a grain) per dose, as in Case 1. The injections were given for 15 days continuously and then discontinued for a similar period. The dose was then raised to three centigrammes (about half a grain), the intervals of treatment and discontinuance being as before, the whole period of treatment extending from May to the end of September. During October considerable amelioration was seen both mentally and physically. The treatment was now reduced to two centigrammes (three tenths of a grain) per dose, and this was continued for seven months. A slight apoplectiform seizure occurred once during this period. At the end of the time it was noticed that the disease (dementia) was arrested, though the patient's original character and disposition—viz., those of a neuropath—were clinically unmistakeable. Professor Lemoine gives detailed accounts of four other cases of general paralysis treated as mentioned. In all the six cases he observed marked improvement of symptoms both mental and physical, but, as he points out, longer periods of observation are necessary before it can be conclusively established that the disease has been definitely arrested in such cases. The excellent results obtained, however, in these cases of general paralysis he regards as justifying publication. Of six cases of tabes dorsalis submitted to the same form of mercurial treatment five improved moderately and one very markedly as regards the ataxia of gait, but lightning pains still occurred at times in all and the knee jerks were absent Professor Lemoine uses the benzoate of mercury because it can be injected locally without harm to the patient. He advises deep injection into the subcutaneous tissue and muscular fasciæ, and says that the pain produced is slight Summarising his results generally he thinks that the improvement attained in cases of general paralysis is greater and more striking than in cases of tabes dorsalis.

---

[1] American Medicine, July 19th, 1902, p. 95.

THE FIRST VACATION SCHOOL IN ENGLAND

ALL ratepayers know that the children of board schools have the month of August in every year as holidays A few of the more fortunate ones get away into the country which is obviously the most ideal way of spending the summer vacation But by far the greater number of the London children have no country air to look forward to and spend August indoors, where they are perpetually in their mothers' way or outdoors on the pavements getting into all kinds of mischief quarrelling and fighting Mrs. Humphry Ward has this year tried an experiment at the Passmore Edwards Settlement in Tavistock place of opening a voluntary school during August for the children of the neighbourhood who habitually attend some 10 board schools and three voluntary schools Children able to pay a country visit or those wanted by their mothers for household work were excluded but more than 600 others volunteered with acclamation to attend, and spent happy hours, tinged only with the one disappointment that they could not stay longer for more classes. No punishments were necessary *excellent discipline was maintained*, and the threat of being sent to the head master who had power to dismiss from the school was always found sufficient by the teachers. The children were divided into two classes which alternately worked for two and a half hours in the morning or the afternoon for five days in the week only In the Duke of Bedford's large garden adjoining the settlement we found on the day of our visit five classes happily grouped under trees clay modelling listening to stories *engaged in kindergarten games needlework for* the girls and nature study which was taking the form of a demonstration on tadpoles. In another corner a joyous shouting class was building a range of mountains in the sand heap, the children working with feverish activity in the short half hour at their disposal. In the house we saw many interesting lessons going on, such as housewifery (which includes the washing and dressing of a baby), drawing from memory from previous lessons and copying flowers, singing to the piano, gymnastics in a fine gymnasium, drilling dancing and carpentering Among the favourite classes for both boys and girls was cooking in the kitchen where the boys proudly showed us the baked savoury mince and the plum pudding which they had just learned to make. A dramatic class was rehearsing a scene from the *Midsummer Night's Dream* which was eventually acted for the benefit of the parents, and another favourite half hour was that spent in the library well stocked with story books The various so-called lessons were all carefully chosen to employ the children's muscles rather than their brains and all lesson books were rigidly eschewed. The children varied in age from six to 13 years, infants not having been accepted. A trained nurse was on duty all through the day ready for the reception of any sick children she was also responsible for the cleanliness of the lavatories and general hygiene. Parents of the children stated that they had never had such a peaceful August before and *the general success of the experiment seemed to be greatly* due to the perfect organisation shown by Mr Holland the head master He was ably aided by 12 teachers and four assistants who were paid out of a small fund raised by Mrs. Ward and her personal friends The cost amounts to about £60 a week, which is much the same as the expenditure in the New York and Chicago vacation schools which have been for some years in progress We cordially *sympathise with this experiment, because it* seems to us that it helps in a small way to militate against embryo hooliganism. The children and their parents are ready for an extension of the scheme next year The school buildings already exist the necessary funds for teachers and materials can surely be furnished by the London School Board provided that it is clearly laid down that the children's brains are not to be worked during their one month's holiday but there is one great difficulty which we cannot help foreseeing and that is the supply of teachers, if the movement is to become general. It is obvious that board school teachers should not be encouraged to give up their necessary holiday but it may be quite justifiable to employ as in the late experiment teachers engaged in secondary or middle-class education aided by students from training colleges who usually get at least two months holidays in the summer Are there enough of these to make general vacation schools practicable in London and other large cities?

SMOKE PREVENTION AND PETROLEUM LAMP ACCIDENTS

NOT the least interesting sections of the annual report of the chief officer of the Public Control Department of the London County Council are those relating to the steps taken to prevent smoke nuisance and to the returns showing the number of petroleum lamp accidents investigated by the Council's inspectors It is satisfactory to note that the action taken under the Public Health Act by the Council and by the borough councils during the year ended March 31st, 1902, has resulted in 819 cases of nuisances being reported of which 541 were regarded as serious. Legal proceedings however were taken by the borough councils in only 119 cases and convictions were obtained in 106 of these the total amount of penalties imposed being *nearly* £551. We rejoice to find that the Public Health Committee are considering how they can increase their powers in this matter and it is suggested that the special section of the Act should be so worded as to cover any serious emission of smoke from a chimney Further it is proposed to impose a direct penalty of not exceeding £10 for the first offence, to be increased for subsequent offences instead of applying to smoke nuisance, as at present, the complicated procedure that may be properly applicable to a sanitary nuisance We certainly agree that if the law could be so amended its active administration would at once lead to a considerable diminution of the smoke nuisance which still afflicts London. With winter approaching we trust that a strong endeavour will be made to bring such excellent proposals into effect. Under the same Act proceedings were taken in regard to 74 cases of smoke nuisance arising from railway locomotives. The worst offenders in this respect were the South Eastern and Chatham Company who contributed just one half of the cases and paid accordingly one-half of the total amount of penalties (£230) imposed. The Brighton line comes next then the Great Eastern, then the Southend line (four cases) and the London and North-Western (three cases) The Midland, Great Northern, Great Western, Great Central, and London and South Western railway companies do not appear in the category The number of lamp accidents investigated by the Council's inspectors during the past year was the same as in the previous year—namely 204—whilst the number of fatal cases diminished to 18, in which 21 lives were lost In most cases the accidents were due to cheap lamps, to the penny glass lamp or white china table lamp, or to lamps with thin glass reservoirs The return of lamp accidents does not altogether justify the chief inspector's statement that a remedy for the great majority of petroleum lamp accidents would be found in raising the flash-point and that to deal with the evil solely by means of improvements in lamps will not be effectual. In not a single instance in the lamp accidents is he able to state that the lamp was well made In one case in which two women lost their lives the flash point of the oil proved to be 103° F —that is to say, 3° above the temperature to which it is proposed to raise the flash point In the face of this example, in which the broken lamp had a thin glass reservoir, he states that it is the experience of the department that it is quite exceptional for a lamp in ordinary use to develop such a heat on burning as to raise the temperature of the oil to a point above 100° F In this accident the flash point of the oil was 103° F , while in the two other accidents it was 94° F and 95° F respectively We quite realise that it would be a simpler matter from an administrative point of view to enforce the use of high flash point oil rather than to insist upon the use of properly constructed lamps, but we still believe that there would be greater security in the use of a properly constructed lamp than in the use of oil of 100° F flash-point. Surely it cannot be maintained that the penny glass lamp is safe in any circumstances

TREATMENT OF GONORRHŒA IN THE FEMALE

IN a long article published in the July number of the *University of Pennsylvania Medical Bulletin* Dr W B Small considers the subject of gonorrhœa in the female under the headings of urethritis, cervical gonorrhœa, specific vaginitis, gonorrhœal vulvitis, gonorrhœa of the rectum, and gonorrhœal bubo In the acute stage of specific urethritis the symptoms complained of are frequent and painful urination. Local treatment is contra indicated but a powder consisting of bicarbonate of potassium, bromide of potassium, and salol, five grains of each, may be given every four hours until the dysuria is somewhat relieved The discharge will then be purulent and the urethra may be irrigated with protargol solution, 1 part in 100 or 200, by means of Skene's reflux catheter or a soft rubber catheter Capsules of copaiba and sandal wood oil should also be administered internally After a time injections of sulphate or acetate of zinc, alum, and tannic acid may be employed and continued for two or three weeks If urethro cystitis occurs a solution of protargol of 1 per cent. strength may be applied directly to the bladder wall. Cervical gonorrhœa can only be diagnosed by the help of the microscope. No symptoms usually manifest themselves at the beginning Dr Small recommends that a solution of protargol of 1 or 2 per cent. strength should be injected with a syringe into the cervical canal, injecting very slowly and only while the syringe is being withdrawn, but he admits that this practice is disapproved of by many gynæcologists on the ground of the danger of fluid being forced into the Fallopian tubes If applications of protargol, nitrate of silver, and ichthargan fail, then pure carbolic acid and curetting must be resorted to Specific vaginitis is a disease the existence of which is doubted by some observers, because infection seldom occurs when Neisser's diplococcus is introduced into the perfectly healthy vagina of an adult. Vaginitis, however, assumes a virulent form in infants infected by dirty towels or in consequence of criminal assaults Vaginitis in the infant is difficult to treat, particularly when the vaginal opening is very minute. Weak solutions of boric acid, protargol, and nitrate of silver may be used, together with small suppositories of ichthyol. Gonorrhœa of the vagina in older persons will permit of frequent douching with potassium permanganate, 1 in 2000, followed by protargol, 1 in 100, until the acute stage has somewhat subsided The careful exposure of the vagina, in the knee chest posture, with a specially constructed wire speculum, followed by swabbing the entire surface with protargol, 1 in 20, and placing a tampon containing a weak ichthyol ointment so that the vaginal walls will be separated, is essential. This should not be retained longer than 12 hours and be followed by a cleansing douche of at least three gallons of hot water, then of another quart of mildly astringent douche. Gonorrhœal vulvitis, like gonorrhœal vaginitis, reaches its most pronounced type in the young In the infant a mixture of equal parts of boric acid solution and diluted liquor plumbi subacetatis should be frequently used to cleanse the parts and a few layers of gauze saturated with the same solution should be kept between the labia. In older patients gauze saturated with protargol solution, 1 in 50, should be placed between the labia. In both infants and older patients, after the acute symptoms have somewhat subsided, the parts should be painted with nitrate of silver solution, 1 in 50, followed by a dusting powder composed of equal parts of boric acid and acetanilide Rectal gonorrhœa, which is more frequently caused by the backward flow of the infectious vaginal discharge than through unnatural practices, manifests itself usually by pain and tenesmus In the early stages a solution of protargol of 1 per cent. strength combined with tincture of opium can be used to advantage, followed after the acute stage has subsided by an astringent injection of alum and sulphate of zinc Gonorrhœal bubo in the female does not seem to be as frequent as in the male At the first sign of swelling of a gland complete rest is necessary and an ointment should be applied consisting of equal parts of ointment of mercury, ointment of belladonna, pure ichthyol, and lanolin, spread on lint at least half an inch in thickness, covered with waxed paper, and over this a well fitting pad of cotton wool, the whole being very firmly bandaged with three successive bandages, each three inches in width and eight yards in length. If this treatment is followed for a week without any distinct improvement in the condition the possibility of stopping suppuration is slight.

CHOLERA IN EGYPT

DURING the week ending August 18th the figures for cholera throughout all Egypt were as follows total number of cases, 1127, deaths, 791, and recoveries, 43 The Director General of the Sanitary Department of Egypt writing on August 19th says "In Cairo 150 cases have been announced, against 97 during the week ending August 11th Many of these cases have been found in the villages around Shubra and Abbassieh, and though they figure in the bulletin as coming from Cairo they have not occurred in the city itself, again, others have come into Cairo from infected villages in the Guizeh Moudiria and have died there There has been a marked increase in the number of towns and villages infected during the past week and in those places which depend entirely for their water-supply on surface wells the number of persons attacked has been considerable. During the last week 72 new localities have become infected. Hospitals with accommodation for 840 persons have been distributed throughout the country up to the present"

POTATO POISON

A POISONOUS principle called solanine has long been known to exist in the berries of the common potato plant. Indeed, for the purpose of preparing the alkaloid in the pure state the berries are conveniently employed It may also be obtained from the nightshade and the bittersweet, the kaloid being found in all parts of these common English ants belonging to the solanum or nightshade order Cases poisoning from potatoes are however extremely rare, though those recorded are well defined. It is undoubtedly e case that there is a time when the potato may ntain an important quantity of poison and this appears be when the tuber has begun to germinate and shrivel. In that case the solanine has been found iefly in the peel and at the root of the eyes or shoots. is fact would seem to account for the death of a child cently at Bristol. Amongst other things which she had ten were some potato peelings, and the medical evidence owed that the child died with symptoms consistent with lanine poisoning which are similar to those of strychnine isoning but less acute. An interesting account of the mptoms produced by eating diseased potatoes appeared in e Lancet as far back as 1846 (Feb 14th, p 190) A culiar affection was invariably traced to the use of seased potatoes, being ushered in by rigors hot skin quick lse and abdominal pain. In the next stage rose-coloured tches appeared and as suddenly vanished and in the ajority of cases diarrhœa supervened, in the third stage ere was a swollen state of the muscles of the neck, oulders and arms with pain so acute that the patient inced on the slightest pressure Inability to raise e arms, pains in all the bones, a red erysipelatous ate of the face and skin with œdematous swelling the eyelids so as nearly to close them, were also served. 10 cases of this affection had occurred in ree or four days in the same locality (in Ireland) and all ere similarly affected. The case recorded recently need ive no grounds for alarm, for an actively poisonous potato is uite a rare specimen The poison however probably occurs ormally in the tuber in very small quantity but this uantity may increase to a poisonous amount in the sprout g, shrivelled or diseased potato and then most of it is ound in the skin and eyes. In any case diseased potatoes ould be naturally avoided and they are generally discoloured. The risk, of course, would be greater when such potato is eaten with, as it is often cooked in its jacket.

THE FOURTEENTH INTERNATIONAL CONGRESS OF MEDICINE

The following companies have notified their intention of ffering reductions in railway and other tickets to members who propose to attend the forthcoming International Congress f Medicine. The Northern Railway of Spain and the railway from Madrid to Zaragoza and Alicante offer 50 per cent. eduction. The Transatlantic Company of Spain offers 3 per cent. reduction, and the following French railway companies—the East the South the North the West the Paris-Lyon Mediterranée, and the State and Orléans—offer a reduction of 50 per cent. The General Italian Navigation Company as well as the Puglia, the Napolitana, and the Siciliana Steamship Companies also offer 50 per cent. reduction All information about tickets and similar matters may be obtained from the Voyages Pratiques No. 9 rue de Rome, Paris. Preliminary programmes of the Congress may be obtained from the National Committees in the various countries or by writing to the general secretary at Madrid All notices of papers to be read must be sent to the general secretary before Jan. 1st, 1903. The subscriptions—viz. 30 pesetas—that is to say from 23 to 25 francs according to the rate of exchange—may be sent in to the various national committees or to the general secretary at Madrid.

THE DISTRIBUTION OF PLAGUE

The return of Dr B. Burnett Ham Commissioner of Public Health to the State of Queensland shows that up to midnight of July 7th the total number of cases of bubonic plague reported was 81. The total number of deaths was 25 and the total number discharged as recovered was 56 3800 premises have been cleansed and 2150 loads of filth removed in addition to the ordinary removals of trade and house refuse from within the infected area of the municipality of Brisbane since the end of April. Since January 19,000 rats have been destroyed. 1350 rats have been examined bacteriologically and of these 98 have been found to be infected with plague. As regards Egypt, the returns for the week ending August 17th have been as follows number of new cases 3—all Europeans, number of deaths 1 number of recoveries 5 and total cases under treatment 10 With regard to sanitary measures 13,266 rooms were disinfected and 75 were lime-washed 115 sacks of effects were disinfected and 7792 sacks of rubbish were burnt. The number of rats killed and burnt was 942. As regards Hong Kong a telegram from the officer administering the Government, received at the Colonial Office on Sept 2nd, states that for the week ending August 30th there were 8 cases of plague with 8 deaths.

LEONARDO DA VINCI AS AN ANATOMIST

Messrs Roux and Viarengo of Turin have recently published an edition of Leonardo da Vinci's Dell Anatomia." Like Goethe, the consummate painter was profoundly interested in the structure of the human subject, as well as in its relations to lower organisms and the volume before us (of which but 400 copies have been issued) contains matter enough to leave it doubtful whether the artist of the Cenacolo might not equally have distinguished himself in the field so fruitfully cultivated by a Cuvier or a Darwin The Dell Anatomia" is the reproduction, with 79 tables in heliotype of Leonardo's original quaderni (sheets) preserved in the Royal Library at Windsor 193 drawings by the master being also reproduced in facsimile These, as he tells us in so many words, form part of his studies in the bones, the muscles the nerves the veins the arteries and the viscera of the *corpus humanum*. His peculiarly difficult manuscript has been skilfully deciphered the text transcribed, and the reading of it made easy, by Professor G Piumati who has also annotated it in the most helpful manner with the coöperation of M Th. Sabachnikoff. The all accomplished artist of the Renaissance appears to exceptional advantage in the Dell Anatomia," showing himself as a precursor in the path in which modern science has won so many trophies In lofty disdain of theologian and schoolman alike he brushes prevailing superstition aside, proclaims in language worthy of Darwin the unity in variety" of living species and sets forth a description of man while describing concurrently those animals which are almost a similar species *(che son quasi simile specie)* like the baboon the ape and their many congeners" To confirm his induction he draws the arm of an ape and that of a man placed one over the other demonstrating the greater strength of the former He gives us an admirable description of the tongue as the organ of speech arguing how its modifications coincide with the varieties of idiom or rather dialect between one people and another, how the intermingling of men due to invasions and wars of conquest leads to linguistic developments and how languages decay like the mortals who speak them. In the words of Horace—

> mortalia facta peribunt
> Nedum sermonum stet honos et gratia vivax

Touching in its simplicity is his account of his modes of research clinical and other He would go to the bedside of the dying to ascertain how the "vital spark" was extinguished and tells how he sat beside the pillow of an old patriarch in the Hospital of the Santa Maria Nuova in Florence and gently interrogated him from time to time to analyse his sensations While he was thus engaged the old man (such are Leonardo's words) "in the act of seating himself on a bed, without other movement, and without any accident, passed from this life" Leonardo lost no time in making the necropsy to determine the cause of "so sweet a death" (*di si dolce morte*) and found it in "defect of the blood which sustained the heart." We have, we think, quoted enough to prove the interest of the "Dell' Anatomia" to all students of the history of medicine as well as to those others who would promote a better understanding between fine art and science

THE PREVALENCE OF SMALL-POX

THE following figures show the number of patients admitted to the various hospitals of the Metropolitan Asylums Board for the dates mentioned. On Saturday, August 30th, there were 2 fresh cases, on Sunday, the 31st, there were no fresh cases, on Monday, Sept 1st, there were 2 fresh cases, on Tuesday, the 2nd, there were 3 fresh cases, and on Wednesday, the 3rd, there was 1 fresh case The number of cases of small pox intimated to the Local Government Board for Scotland from August 16th to the 31st inclusive was 7, of which 5 came from the county of Edinburgh and 2 from the county of Lanark

AT a meeting of the United Grand Lodge of English Freemasons on Wednesday last, on the proposition of the R.W Deputy Grand Master, the Earl of Warwick, the sum of 500 guineas was voted to the fund raised by R.W Bro the Lord Mayor of London towards the King's Coronation gift which is to be devoted to the aid of the metropolitan hospitals Grand Lodge has on previous occasions made very handsome contributions to His Majesty's Hospital Fund for London

MR. JOSEPH SMITH, M.R.C S Eng, D P H. Camb, &c, Bedford park, Chiswick, late President of the Incorporated Medical Practitioners' Association and President of the Society of Members of the Royal College of Surgeons of England, is a candidate for the seat on the General Medical Council shortly to be vacant owing to Sir Victor Horsley's term of office coming to an end.

THE dinner and presentation to be given to Mr Alfred Willett by his former house surgeons on the occasion of his retiring from the post of surgeon to St Bartholomew's Hospital will be held at the Imperial Restaurant, Regent-street, London, W, on Tuesday Sept. 30th, at 7 30 P M

Dr Francis William Clark, the medical officer of health of Hong Kong and Dean of the Hong Kong College of Medicine for Chinese, has been appointed a member of the Legislative Council in the room of Mr F J Badely, resigned.

THE annual dinner of the members of the medical profession of Leeds and district under the presidency of Mr Edwin Lee of Dewsbury, with Mr Mayo Robson as the principal guest, will be held on Wednesday, Oct. 1st.

CONVALESCENT HOME AT SWANSEA —The Lord Lieutenant of the county of Glamorgan (Lord Windsor) on August 30th laid the foundation stone, on the hillside above Cwmdonkin Park, Swansea, of a convalescent home to be used in connexion with the Swansea Hospital. The establishment of this new institution for Swansea has been rendered possible chiefly by an anonymous donation of £10,500 This has been supplemented by other subscriptions intended to allow of the original gift being reserved for the maintenance of the institution, while the site has been secured free of cost from the corporation.

THE CASE OF DR W T LAW

A MEETING of sympathisers with Dr W T Law was held at the Gordon Room of the Holborn Restaurant on August 29th, Sir William S Church, Bart, being in the chair

SIR WILLIAM CHURCH said that they had met to take part in the concluding act of what had been a very unpleasant and regrettable incident—regrettable, not only for the trouble and anxiety it had caused Dr Law, but also because it touched the honour of the profession They had come together to show their sympathy and he was glad to say in a substantial and tangible way, with Dr Law in his disagreeable position, in which through no fault of his own he had been placed He (the speaker) could not believe that the poor weak woman to whom not for weeks or months only but for years Dr Law was so attentive and kind was the real plaintiff—she was but the means through which others could attack him The medical profession was always liable to attacks of this kind, however confident they might be of the uprightness of their motives and actions they were liable to be misrepresented and the moral they should draw from this and other similar cases was that whatever might be their position they should protect themselves, as they did their property by insurance, by joining medical defence unions Dr Law had come successfully and triumphantly through the ordeal, but it was not possible in many cases for individuals adequately to defend themselves They congratulated Dr Law most heartily on the outcome of the proceedings so vexatiously brought against him

Dr R PARAMORE said that it gave him great pleasure to see in the chair such a distinguished member of the profession as the President of the Royal College of Physicians of London He was glad to say that the Law Fund was in his opinion a great success There were difficulties in the way which had to be overcome There was the erroneous impression that Dr Law did not need assistance Some, too, considered that he ought not to be helped because he had not availed himself of the advantage of joining one of the excellent medical defence societies Yet they had met that day to celebrate not merely a brilliant pecuniary achievement to the extent of more than £700 but a grand "moral victory"

Mr J S COTMAN, the chartered accountant, having read his report

Dr J G GLOVER proposed the following motion —

> That this meeting rejoices at the success of the Law Fund and congratulates Dr W T Law on the practical sympathy he has obtained from nearly 700 members of the medical profession, besides some members of the public

Dr Glover thought that the movement had proved a great success and one that showed what the profession could do when it recognised its own solidarity and put its shoulder to the wheel The contributions came from all classes in the profession—from consultants like the chairman and from hard working general practitioners It would be easy to under rate the sacrifice implied in such a subscription list on the part of many practitioners whose work was hard and whose income was altogether disproportionate The result reminded him of a similar success some years ago in a case taken up very heartily by Sir William Jenner, then the President of the Royal College of Physicians of London, whose successor as well as the President of the Royal College of Surgeons of England and the Master of the Society of Apothecaries had given their hearty and valuable help Dr Glover strongly endorsed the advice of Sir W Church that all practitioners should protect themselves by being members of one of the efficient defence unions of the profession History showed that even eminent consultants as well as general practitioners were liable to the risk of unprincipled and ungracious prosecutions. Reverting to the success of the fund it was satisfactory to recognise the sympathy of the public This was shown by the action of the jury and the words of the judge at the trial as well as in the subscription list. He had much pleasure in proposing the motion.

Dr W EWART, in seconding the motion, referred to the gratification experienced by those who were present and a large body of sympathisers at the thought that Dr Law had been effectually helped by the fund, and that after the severe strain which he had undergone he was able to attend the meeting in unimpaired health and spirits

Mr CHRISTOPHER HEATH proposed—

> That the best thanks of this meeting be given to the Editors of THE LANCET, the *British Medical Journal*, and other medical papers for the invaluable aid they have given to the movement.

Mr Heath had much pleasure in bearing witness to the powerful influence for good that the medical press possessed and how wisely and generously it used its ability not only for the benefit of the profession but for the public welfare

Mr ONSLOW WICKHAM said that he had much pleasure in seconding the motion. Medical men had read with sympathetic interest what had appeared in the medical press relative to Dr Law

Sir WILLIAM CHURCH then presented a cheque for £500 (signed by himself, Sir H. G Howse, Dr Burton Brown, and Dr. Paramore) to Dr Law who had previously received £110 The balance of the fund will be duly paid after the expenses have been deducted.

Dr LAW in acknowledging the presentation, said that his heart was so full that he felt it difficult adequately to express his sense of gratitude to those members of the profession who had so generously come forward in his behalf in raising so handsome a sum as had been presented to him He also wished to express his grateful acknowledgments to Sir William Church for his great kindness in coming that day to preside over their gathering and also for having associated himself with Sir H G Howse, President of the Royal College of Surgeons of England, and Dr Brown until recently Master of the Apothecaries' Company as official custodians of the fund. To both these latter gentlemen also he desired to offer his most sincere thanks Although not strictly germane to the matter in hand he would like publicly to express the deep obligation that he felt to those members of the profession who so freely came forward at the trial to support him as witnesses, and though very few were called because the jury stopped the case he was none the less in their debt Without the help of his medical brethren at that time the result might have been less satisfactory than it was. With regard to the splendid gift which he had just received there was one man to whom he could not sufficiently express his deep acknowledgments and that was Dr Richard Paramore his old friend and fellow student To his untiring energy enthusiasm and devotion was due the wonderful success attained and he should always feel the deepest gratitude to him. To Dr C Theodore Williams, Dr R. A. Gibbons, and Mr H C Mends Gibson he was also under obligations of a very special kind for most valuable help and sympathy He desired, in conclusion to express through that meeting his sincere and heartfelt thanks to all those members of the profession who had so kindly and generously helped him in his troubles

Dr EWART proposed the following motion which was carried by acclamation —

> That the thanks of this meeting and of the subscribers to the fund be awarded to Dr Paramore for the good work he had done in initiating the fund and in making it so great a success

Many had felt for Dr Law but their sympathy could not have taken a practical shape but for the opportunity which had been given to them by Dr Paramore s energy

Dr BURTON BROWN said that he had the greatest pleasure in seconding the motion for a vote of thanks to Dr Paramore for his very successful and great efforts in advocating Dr Law s cause and obtaining this fund.

Dr PARAMORE, in reply said that it was very gratifying to him to know that his efforts had been so successful. These prosecutions would never occur if medical men would do to each other as they would be done by

The meeting closed with a motion proposed by Dr LAW thanking Sir William Church for his services in the chair The motion was seconded by Dr GLOVER who was pleased to think that it was on his suggestion that the heads of the medical corporations had been asked to accept the duty of trustees of the fund. It would be well for the profession if its official chiefs and the great body of members could always act together

Sir WILLIAM CHURCH in responding said that what he had done was nothing compared to what others had done in the matter and it was a pleasure for him to be present and to assist as far as he could.

Dr PARAMORE proposed a vote of thanks to the proprietors of the Holborn Restaurant for generously lending for the second time the use of one of their magnificent rooms without payment, and this was carried with cheers.

THE ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD FOR THE YEAR 1900-1901 [1]

SECOND NOTICE.[2]

IN the first notice of this report a general account was given of the contents of the volume and reference was made to some of the researches which were carried out by the scientific members of the staff with a view to improve the quality of the lymph which is supplied by the vaccination department for the use of the public. The energy displayed by the department in regard to this subject forms a marked contrast to the apathy of the people. Whilst every effort has been made on the one side to increase the efficiency of the lymph and to minimise the risks of the operation on the other there has been an increased tendency to avoid the benefits freely offered. The moral weakness of a Government with a strong majority fostered and encouraged the prejudices of the foolish and of the ignorant Conscientious objection to vaccination under the Vaccination Act of 1898 was allowed to take the place of the operation itself for it became 'registrable —that is to say an official record of the objection became equivalent in the eyes of the law to vaccination itself. The Act came into force on August 12th 1898 ,and Mr W H Power's report shows that thereafter for four months it was open to parents to apply for certificates exempting from vaccination children born before the passing of the Act The effect of this law was that no less than 203,413 certificates of conscientious objection relating to 230 147 children were received by vaccination officers in England and Wales.

In the present report there is a digest of the vaccination officer s returns with regard to children whose births were registered in the year 1898 (Appendix A, No 1 p. 1) and a similar digest for the year 1899 (No 1 Appendix A, p 21) The latter is introduced by a rather curiously worded preface which tells us that this digest which is subject to correction was able to be inserted just before the volume went to press. The inference seems to be that the digest has been promptly if not hurriedly prepared and that perhaps a tribute should be paid to the despatch with which the work has been done and that due allowance ought to be made should it hereafter prove that it is in any respect inaccurate It is, of course evident that a large mass of figures had to be dealt with but the fact that the digest of the returns for the year 1899 are not published until the second half of the year 1902 appears to savour rather of delay than of promptitude.

The summary of the vaccination officers returns for the years 1898 and 1899 is given below In order at the same time to save space and to show at a glance the corresponding figures for these two years those having reference to the latter year are in each case printed within brackets

Of 923,059 (929 189) births returned to the Board by the vaccination officers in *England and Wales as registered* during the year 1898 (1899) the number which at the time the return was made had been registered as successfully vaccinated was 562,737 being almost 61 0 per cent. of the whole (617 113, being 66 4 of the whole) and the number registered as having died unvaccinated was 110 912, or 12 0 per cent. of the whole (113,616 or 12 2 per cent. of the whole). Of the remaining 249 410 (198 560) children 3232, or 0 35 per cent. of the whole (5379 or 0 6 per cent of the whole) had been registered as insusceptible of vaccination 4 (4) cases as having contracted small pox 16 921 or 1 8 per cent. (16 005 or 1 8 per cent.) as having their vaccination postponed by medical certificate and 47 423, or 5 1 per cent. (33 673 or 3 6 per cent.) in respect of whom certificates of conscientious objection were received leaving 181 830 or 19 7 per cent. (142,939 or 15 6 per cent) as removed not to be traced " or otherwise unaccounted for If from the 923,059 (929 189) births returned by these officers deduction be made of the deaths that took place without vaccination, it appears that, of the surviving 812,147 (815 673) children there were registered at the time of the return 69 3 per cent (75 7 per cent.) as successfully vaccinated, 0 4 per cent. (0 7 per cent) as either insusceptible of vaccination or as having had small pox, 2 1 per cent. (2 per cent) as under medical certificate of postponement, and 5 8 per cent. (4 1 per cent.) in respect of whom certificates of conscientious objection to vaccination had been obtained, leaving 22 4 per cent. (17 5 per cent.) as at that time still unaccounted for as regards vaccination

---

[1] Thirtieth Annual Report of the Local Government Board 1900-1 Supplement containing the Report of the Medical Officer for 1900-1 London: Eyre and Spottiswoode 1902 (Cd [illegible] Price [illegible])

[2] The first notice was published in THE LANCET of August 23rd 1902, p. 5[illegible]

The proportion of cases unaccounted for in the metropolitan returns for 1898 is 31 2 per cent (for 1899 it is 27·7 per cent.), in the provincial returns 19·6 for 1898 (and 15 4 per cent for 1899)

It must be admitted that to the vast majority of people large numbers of figures presented in tabular form are puzzling rather than interesting, but even the vaccination tables contain some curious pieces of information which are worthy of note One such fact is that the objection to vaccination affects some places markedly more than others The returns of the year 1898 show that the number of births in Leicestershire was 12,878, and of these children only 1228 were successfully vaccinated and four were stated to be insusceptible to vaccination No less than 3661 certificates of "conscientious objection" to vaccination were received and the number of the children who died unvaccinated (1874) was greater than the total number of children vaccinated. Finally, for the series of years (1893–97) a huge number of children remained unaccounted for when the returns for the years were received, the number amounting to no less than 72 per cent. of the total number In Rutlandshire for the same period the corresponding percentage was 5 3 In London the proportion of children 'unaccounted for" has also been found to vary greatly in different parts of the town, from 5 3 in St. George's, Hanover square, to 68 2 in Bethnal Green

Mr Power calls attention to the fact that the metropolis is at a disadvantage as compared with the country at large in regard to the protection against small pox adopted for its infant population. The popular appreciation of the benefits of vaccination is making no progress, on the contrary, unless an alteration has taken place since the collection of the statistics given in the present volume, it is evident that there has been a regular and steady decrease in the adoption of vaccination This is very clearly shown in a table given by Mr Power which is quoted below

Periods	Percentage	Abstention from infantile vaccination
	Metropolis	Rest of England and Wales
Average of 1873–77	8 1	4 1
, 1878–82	6 8	4 4
1883–87	7 4	5 7
, 1899-92	14 1	11 2
Single year 1897	23 9	19 7
, 1898	34 4	25 4

The report gives a good deal of information in regard to inspection of public vaccination, particulars as to education in vaccination, an account of the work done at the animal vaccine establishment and of the changes which have taken place in the composition of its staff and in its working arrangements

The reports of the medical inspectors of the Department are always full of interest and full of instructive details Mention has already been made of the fact that some of the inspectors whose reports are especially marked by great ability and thoroughness have during the year under review been engaged in other work, but it is pleasing to note that the best traditions of the medical inspectors of the Board are in several cases being carried on without a break. The amount of what may be called routine work which has been done may to some extent be gauged by the fact that 21 sanitary districts were visited by the medical inspectors with special reference to outbreaks of infectious disease and to general sanitary circumstances and administration, local inquiries were held in connexion with the provision of hospital accommodation at 64 places, in five places inquiries were made with reference to sewage disposal, in two districts local inquiries were made in regard to water-supply, in four places inquiries were made in regard to scavenging, in five places investigations were made as to the desirability of adopting the Board's model series of by-laws, special visits in regard to vaccination administration were made in 16 places, 57 port and riparian districts were visited in regard to special precautions against the plague, and 17 conferences of sanitary import have been held with local officials

The abstract of medical inspections made in 1900 with regard to questions concerning the incidence of disease on particular places and to questions concerning local sanitary administration contains information as to the condition of 15 places which for various reasons were specially brought to the notice of the Local Government Board At Bishop's Auckland (in Durham), which has a population of 10,000, enteric fever was prevalent during the years 1898, 1899, and 1900 An inquiry into the cause of the visitation was instigated at the instance of the Durham County Council Dr S W Wheaton found that the water supply was derived from the river Wear, which was much polluted, and that the water was not always filtered before its distribution, that the sewers were made of tile and rubble, that the house drainage was defective, and that the contents of the privies were thrown into yards and into the streets There was no disinfecting apparatus Dr Wheaton attributed the outbreaks of typhoid fever to the contamination of the water supply

An inquiry was held at Failsworth as to the supposed inadequate remuneration of the medical officer of health The amount of the salary is not stated in the report, but Dr W W E Fletcher was of opinion that it was insufficient in amount In the course of this inquiry information was obtained which should prove of interest to the inhabitants of the important borough of Oldham The Failsworth district is supplied by the water mains of the Oldham corporation and Dr Fletcher reports that this water is derived from gathering grounds and supplied unfiltered.

In the Farnworth urban district (Lancashire) an inquiry was instituted in consequence of the prevalence of typhoid fever Dr Fletcher found that the water supply was obtained from the mains of the Bolton corporation and that the gathering ground from which the water comes is not free from the risk of contamination. Dr Fletcher reports that enteric fever has for some years past been endemic in the Farnworth district and that it has not assumed epidemic proportions, he suggests that "probably it has been fostered by the system of excrement disposal in vogue in the district" This is rather a dark saying It would be well if the corporations of Oldham and of Bolton would take all necessary precautions to ensure the absence of pollution from the gathering grounds from which they derive their water It is not only more safe, it is also less expensive to undertake such work before the outbreak of an epidemic In the case of the Bolton water it is distinctly stated in the report that there is risk of contamination, and although little information is given in the case of Oldham it would be well for the corporation to appreciate the fact that filtration of the water would not be disadvantageous

At Hexham in Northumberland there was an outbreak of typhus fever The source of infection was almost certainly traced to a gipsy encampment, and from the first case infected at Hexham a definite chain of infection was established Most of the cases occurred in some insanitary and overcrowded property There were altogether 32 cases and five deaths All the fatal cases occurred in people over 40 years of age At Llangattock in Brecon an inquiry was made into the cause of the prevalence of diphtheria. Many cases had occurred there and it was shown that the sanitary condition of the place was generally defective

At Pennal village (Merionethshire) and Pontypridd (Glamorganshire) inquiries were made in regard to the undue prevalence of diphtheria In both these instances there was deficient provision for isolation. At Prestwich urban district, Lancashire, where diphtheria was also unduly prevalent, the sanitary conditions were found to be defective, but active measures were taken to prevent the spread of the disease by infection The Romney Marsh rural district of Kent came under the notice of the Local Government Board because they refused to appoint a single medical officer of health for their whole district, and concerning the point at issue they made a statement which Dr Darra Mair states he "found to be untrue" The district is a large one including nearly 30,000 acres, and the population, which numbers 2893, is widely dispersed through it the most populous village containing only 560 persons. The general sanitary condition of the district is unsatisfactory, and it is obvious from the report that an energetic medical officer of health and an active inspector of nuisances might find plenty of work in the marsh. The Romney Marsh rural district council has no desire to pay such officers and it is not certain that it would not prefer to do without them

At Nailsworth in Gloucestershire an inquiry was instituted in regard to the general conduct of the urban district council. Dr F St. G Mivart found that the method of excrement disposal varied. Some of it was thrown on to small gardens, some was conducted through short sewers to a stream which flowed through the town, and some passed into a pond which communicated with streams The local authority maintained that the sewers were practically untainted and that there was no reason for entertaining any *drainage scheme.* At Nuneaton and *Chilvers Coton,* an urban district in Warwickshire, having a population of 15 000 typhoid fever was prevalent during the year 1899 and 16 deaths occurred amongst 114 cases. Dr. R. W Johnstone ascribed the outbreak to pollution of soil, personal infection and pollution of well water

The Stroud (Gloucestershire) rural district council made a complaint of the sewage sent down from Nailsworth. This district contains a population of 30,000 and the sanitary arrangements leave much to be desired. Excrement is disposed of either by discharging it into streams or into fissures in the limestone rocks Sewerage is very limited but its extension *has* been planned and is impending *as Dr* Mivart reports. ' Impending ' is rather an ominous word It may be hoped that the sewers, if extended, will be so laid that the sewage will pass in the desired direction. This point, though of importance, is often neglected in country towns and in rural districts

Two of the most interesting and the best written reports are that on the borough of Boston (Lincolnshire) by Dr S Monckton Copeman and that on the Northam rural district (Devonshire) by Dr R J Reece. The inhabitants of Boston have suffered much from typhoid fever and from diarrhœa and the corporation has failed to comply with recommendations which have previously been made to it as the result of the former investigations of the medical inspectors of the Board. Boston is a low lying town, situated on the river Witham, and has an estimated population of 16 000 and a rateable value of £47 240 The ancient waterways have been to some extent used as sewers and in places these have been covered by buildings. The condition of things seen in parts of Boston to-day closely resembles that which existed in London when the Fleet stream was encroached upon by the adjacent land owners There is at Boston a court of commissioners of sewers and the dyke reeve, an official of the court, has charge of dykes and sewers. The sanitary authority of Boston appoints members to the court but has no direct authority over the officers. The bacillus coli has been frequently found in the drinking water which is supplied by a company An ingenious explanation has been offered as to the presence of this bacillus in the water It was observed that hares browsed in the early morning on the sloping sides of the reservoirs of the company It was suggested by the manager of the water works that the evacuations of these animals might supply the bacillus The company it is said then adopted the precaution of putting up wire-netting to keep off the hares. The investigation into the general sanitary conditions of Boston was made with great care and ability and the report is well worth reading It is not possible to devote the space necessary to summarise it here and it can only be said that the present state of Boston is in every respect deplorable. The town council would be well advised to carry out the recommendations which it has received The Council, however do not think that any fresh system of town drainage would lessen the sickness or make the town more healthy " This view is unduly pessimistic A council so wise in its own conceit often requires the immediate presence of a fearful epidemic to make it alter its opinion. Such an epidemic may be expected. Boston is not a residential place " nor is it overcrowded with visitors. The few who go will for the present do well to avoid drinking water whilst there and to sleep elsewhere. The smells of Boston resemble those of Bruges, but the other points of interest are less numerous

An excellent account is given of the sanitary condition of Appledore, a small port in North Devon situated at the junction of the Barnstaple and Bideford rivers. The inquiry arose from the fact that the reports of the medical officer of health of the Northam urban district (which includes Appledore) were deficient in regard to information required by the Local Government Board to enable an estimate to be formed of the sanitary condition. The Northam district comprises Westward ho, a comparatively new and newly named resort well known to all who as play at golf Northam, a hill village Northam Ridge, a rural district and Orchard hill, a residential neighbourhood. Appledore was reported upon in the year 1871 by *the* late Sir Richard Thorne and in 1894 it was visited in the course of the cholera survey At the time of the latest survey the sewerage system of the town was found to be not in accord with modern requirements and there was a scarcity of water The medical officer of health of the district was 72 years of age on his appointment and he receives an honorarium of £10 per annum. He was a native of Appledore and *commenced his professional training in the year* 1843 when he was indentured to his father In later years Dr Reece thinks that his professional work has not been such as to keep him instructed as to the progress of sanitary knowledge and his annual reports have not given information as to the hygienic condition of his district of the work carried out for the improvement of the sanitation or of the measures which ought to be adopted. In regard to infectious diseases the medical officer of health has in Dr Reece's opinion, *acted* under the mistake that it was his duty to visit and examine patients whose names have been ' notified " to him and to *revise* the diagnosis should occasion require. *The sources of the water supply at* Appledore *were open* to contamination and the amount obtained was insufficient, but work was in progress to obtain an adequate supply from a distance.

THE TRANSACTIONS OF THE BRITISH CONGRESS ON TUBERCULOSIS, 1901 [1]

INTRODUCTION

WE published last year a full account of the proceedings at the British Congress on Tuberculosis recognising that the Congress was an opportune and admirable recognition of the determination recently arisen among civilised nations to fight systematically against a devastating disease. The Congress was, in fact, not so much a meeting of scientific men to discuss therapeutic measures—though it was of course this—as an expression of the feeling that Governments and peoples must support their sanitarians and reinforce their measures of State medicine if tuberculosis is to be prevented from exacting year by year a terrible toll of lives which could be saved by preventive measures. The official transactions of the Congress have now been published as we have already announced and a review of the four volumes now before us gives us an opportunity of estimating the value of the work done and making a more or less general summary of the proceedings that took place under the headings of medicine and pathology

For example, the various communications dealing with the uses of tuberculin show how much there yet remains for the practical pathologist and physician to do before a definite decision can be arrived at Again with regard to the influence of climate upon tuberculosis and the part played by the sanatorium treatment, we get by studying these transactions and comparing the different experiences of physicians of various nationalities an all round idea of the value of systematic treatment that no previous work has offered The published proceedings of the Congress confirm the opinion that we expressed last year that the work done by the Congress was of incalculable use to the cause of preventive medicine and we trust that future international deliberations will be held in support of a continued movement of civilisation against its great enemy—tuberculosis.

TUBERCULIN

A discussion upon tuberculin in which the Sections of Medicine and Pathology were supposed to combine appears to have been left entirely in the hands of the physicians and to have been carried on from the clinical point of view Laboratory work is represented by a paper upon Immunity and Sero-therapy in Tuberculosis from Dr Katsuralaro Yabe chief medical officer of the Japanese Navy This work from M. E. Roux's laboratory by analysis of bacilli finds (*a*) a tuberculo mycoprotein which provokes leucocytosis at the point of injection and (*b*) a nuclein like bacterocidin which induces obliteration of blood vessels The former induces some immunity of an antitoxic, and the latter some of a bactericidal, character

---

[1] Transactions of the British Congress on Tuberculosis for the Prevention of Consumption London, July 22nd to 26th 1901 Vol I to IV Edited by the Honorary Secretary-General. London: William Clowes and Sons Limited. 1902.

Immunity is not readily perceived , its existence is shown by the phenomenon of Koch in the guinea-pig This investigator obtains a serum by injecting the above constituents of bacilli into goats He then treats guinea pigs with the serum, some before and some after infection with tubercle , some of the former showed effects by their survival, but none of the latter At present he states that he has found nothing for therapeutic use

Many medicinal preparations from cultures of tubercle bacilli have been used by Dr Charles Denison , he tabulates his experience in 200 cases It is difficult to compare these results , perhaps they are equally favourable and promising

In the discussion while the most experienced in the use of tuberculin were also those who saw most benefit in the drug, none provided a clear comparison of similar series of cases treated with or without tuberculin Seeing the advance now in other methods such a comparison will take years longer to be effected. The impression given by this discussion may well be stated under those three headings taken by Professor McCall Anderson

1. Is it safe to use tuberculin? Professor W Osler and Dr Moeller had never seen any injurious effects and Professor McCall Anderson said that its use is quite safe This may be taken to refer to the present dosage Professor Koch tells us to commence with one-tenth of a milligramme, to employ it only in a patient without fever, and upon repeating the drug upon the second day not to increase the first dose, as he and many others note that the same dose frequently gives a more severe reaction upon the second occasion. Dr Moeller quotes a case in which it was weeks before the repeated injection of one twentieth of a milligramme failed to give rise to fever, and Dr G A Heron a case in which an initial dose of one third of a milligramme in an enfeebled and severely affected patient was followed by a rapid deterioration which he considered to be unexplained. In the last instance the dosage exceeded the limit now given by Koch and perhaps the new limit will not give rise to those experiences which led Dr W R. Huggard to discontinue its use.

2 What is its diagnostic value? Dr Eric France has fully shown its trustworthiness by testing 75 patients, tuberculous or non tuberculous, one half of whom have since died and upon whom necropsies have been made. Dr A. K. Stone pointed out that small inconsequential lesions may give very misleading information in important cases Such an experience is no doubt unfortunately possible , at the same time it may be thought that such cases as Professor McCall Anderson gave instances of—doubtful lymphadenoma and doubtful lupus—are very prone to undergo mistaken treatment unless this test be employed, and its occasional careful use may become more general with advantage.

3 What is its therapeutic value? Dr Heron reported in full 31 cases in 1890 and seven years later one half of those patients could be traced and were well , such a London hospital experience of pulmonary tuberculosis is remarkable Nearly three fourths of the patients in a series of 200 cases treated in the last 10 years by Dr Goetsch were quoted to be well , these were treated with doses of only 0 00001 gramme of old tuberculin as a rule , they were treated for a few weeks or months and after an interval again for a term So long a duration must be compared with sanatorium treatment, which in selected cases will claim equally good results It seems evident that the question can only be threshed out in a sanatorium which will for a term simply add this treatment to its other methods

Empiricism in tuberculin administration seems to teach us that the local effects upon the tubercle must not be gross and palpable , perhaps even a dose not sufficient to induce fever is best. If the latter prove to be the case a more extended usefulness may be found and those who must be out-patients might be treated with it. If this agent, which induces in the guinea pig the phenomenon of Koch, in dogs an amelioration of experimental tuberculosis of the peritoneum described by Dr Denys, and in man the inflammatory reaction round a tuberculous focus or nodule of lupus tissue, should continue to have no therapeutic use it would be an *opprobrium medicorum*

Professor Koch has formulated the present rules for treatment. He restricts its use to cases definitely without fever and cases not advanced in disease The lessened dose and lessened reaction or no reaction afford a treatment quite different from that introduced 12 years ago as tuberculin treatment Dr Heron remarked how tuberculin had been both made and unmade in Germany So far as the Congress assisted in the re making it is gratifying to see Great Britain providing apparently as much information as Germany

A change of view is being put forward now which draws attention to other organisms as much as to the bacillus of tubercle Professor Koch spoke of morbid processes caused by even streptococci and staphylococci rendering a case unsuitable for tuberculin treatment, and such mixed infection he considered to be the usual associate of the symptom—fever Professor Nolen uttered a warning against viewing every feverish reaction as evidence of mixed infection. Sir R. Douglas Powell referred to the great importance of mixed infection. What is its importance? Are we to consider that the additional organisms deserve the most attention or are they but unimportant epiphenomena?

In the hope of finding some elucidation of these secondary infections so often referred to in the discussion upon tuberculin we turn to the Transactions of the Section of Pathology, where it has a place upon the programme of discussions The able opening of the subject by Mr A. G R Foulerton met, however, with little seconding or response and elucidation is limited to the contribution of the opener and a valuable paper by Professor Ophüls. The multiplicity of data—clinical, histological, and bacteriological—that demand investigation in each case is so great and the problems then presented by the facts elaborated are so abstruse that few could be found who had elaborated these studies and were ready to respond to the challenges thrown out by the opener of the discussion.

Mr Foulerton finds in secondary infections the main explanation of the symptoms and course of most cases of pulmonary tuberculosis , other competent investigators, on the other hand, deem them to be most subsidiary factors It follows according to Mr Foulerton's point of view that the treatment of pulmonary tuberculosis, especially sanatorium treatment, owes its success to its influence upon secondary infection While we know to some extent the influence of treatment upon the bacilli of tubercle and their disappearance from the sputa, we have not any account of the disappearance of the secondary organisms There are five common predominating organisms of secondary infection and several not so common. If they do so dominate the position wonder may be expressed at their family likeness in symptoms, and still more at the clinical discrimination that had named as phthisis exactly that ailment which held the bacillus of tubercle in evidence after Koch's discoveries

Professor G Sims Woodhead points out that although the most infective of these secondary organisms, the streptococcus pyogenes, is common, pyæmic abscesses do not occur, and Mr Foulerton declared general blood infection not to be a factor of any consequence That by no means a little information is yet wanting on these topics is emphasised by the difference of view as to matter of fact evinced by the opener of the discussion and Professor Ophüls , the one does not find active destruction of tissue by pure infection of bacillus tuberculosis, the other does This difference of opinion may be removed suggests Professor Ophüls if it be admitted that the damage done apparently by pure tubercle is really due to pyogenic organisms that have disappeared. How deeply yet, then, must the pathologist delve before he can give the clinician light on this question

In the contribution of Professor Ophüls the most valuable researches into 39 cases (consecutive cases) have been made It is well for the reader to turn to the synopsis of cases classified according to their infection and whose symptoms are noted Let him see if the clinical history will afford a diagnosis of cases of mixed infection from others , we are conscious of an inability to find it It is evident that this field of pathogenesis must await future congresses for its solution.

CLIMATE AND SANATORIUMS

The Section of Medicine discussed climate—both the effects of climate and the indications for special climates Sanatorium treatment was discussed upon another day

The British physician may be said to have the most widely varied experience of climate, and it was on this account appropriate for the Congress to take up the subject. Dr C Theodore Williams and Dr I Burney Yeo introduced the subject succinctly, but the discussion drifted often into the domain of sanatoriums, and no doubt we shall never in the future be able to discuss these questions with so much dissociation as was possible in 1901

It is satisfactory to find that a general agreement marks the opinions expressed, both as to the effects of and indications for climates Sir Hermann Weber agreed with the openers of the discussion that high mountain resorts have the widest range of applicability to moderately advanced cases. The effects of high altitudes were clearly analysed by Dr Amrein and Dr Huggard The heat-abstracting power—with its attendant increased combustion tissue change and, according to Dr Amrein increased quantity of hæmoglobin—is the dominating effect. This low temperature is a tax upon the powers of the patient, and the indications for climate were most frequently discussed in the form of contra indications to high altitude and the inability of the patient to show the requisite powers of heat production Low barometric pressure and cold affect the circulation Dr Amrein in his paper upon the Physiological Principles of High Altitude Treatment told us that in the Alps at Arosa the highest average temperature is only 54° F accordingly it is readily explained that the Alps are contra indicated in cases with organic heart disease feeble circulation and even in patients sensitive to cold A few years of life the difference in the age of a patient from 40 to 50 years, may commonly be accompanied with such diminution of the power of reaction to cold as in itself would no longer *allow of the recommendation of high altitude The dryness* of the air precludes cases with much bronchial catarrh from benefiting largely and it is the same in a catarrh accompanying tubercle of the larynx. Diseases of the kidney and albuminuria are prejudicially affected by cold, so this complication is a contra indication of sojourn in high altitudes. The same cause it may be, places intestinal tuberculosis or diarrhœa in this category Emphysematous cases, advanced cases those acutely febrile and those with large cavities and hæmorrhage may be added to complete a list which should be governed by physiological principles of selection. Dr Theodore Williams s 385 *patients were by no means* quite early cases, one third had excavation, and these resulted in arrest for 20·6 per cent and improvement for a further 41 per cent.

The influence of sunlight and its enhanced power at high altitudes were insisted upon by Dr Denison. Dr Huggard remarked upon the rapid disappearance of slight anæmia, and Dr Amrein recorded the evidence of several investigators to the effect that a real increase of hæmoglobin and corpuscles occurs but seeing that now winter is as effective as summer in the progress of patients at sanatoriums we desire further evidence of the influence of sunlight and its mode of action

Sir Hermann Weber Professor Christian Gram and Dr Armaingaud all reminded the Congress of the seaside sanatoriums and how they are unequalled for surgical tuberculosis and for catarrhal cases of phthisis. The establishment at Margate a pioneer work of more than a century s standing in this country was pointed out by Sir Hermann Weber as an instance of the Englishman s habit of deprecating his own good work, for it has recently been receiving poor support quite unjustifiable in so useful an institution.

Sea voyages were very generally condemned. They no longer consist of a seven *months sailing trip and such discomforts* as those depicted by the late Sir William Flower are too likely to be ill endured.

Desert climates are allowed to have a wide field. Dr Leo mentioned the rheumatic or gouty cases of the fibroid or pleurogenic type as especially suitable. Dr F M Sandwith pointed out that European residents in Egypt are practically exempt from tuberculosis.

Our French *confrères* contributed several interesting papers especially noteworthy being that in which Dr Lannelongue Dr Achard and Dr Gaillard endeavoured to state the effect of climate on the guinea pig in precise terms and to apply the result to man 50 guinea pigs under similar conditions but at three different climates were inoculated with tubercle. The main result was evidence of variability of lesion. To say on evidence of such a nature that climate has been unduly valued seems a *non sequitur* Climate is sought, as we have seen always for the individual and not for the tuberculosis Stamina, absence of catarrh, and healthy appetite are great features in an individual but not in these animals who also are not buoyed up by cheerfulness and hope. At the same time it may readily be admitted with these writers that internal causes—the resistance of the individual—have a greater determining power on the progress of the disease than has simple climate

Various places have their climates described Dr F Allen s sketch of Natal gives us at the same time quite a glimpse of the whole country Dr Stephani gave his results in 150 cases at Valais, Dr Auffret condemned the climate of Brest, and Dr P S. Hichens inquired if any types of pulmonary tuberculosis are unsuitable for treatment in the British Isles

Care without climate is better than climate without care This good aphorism of an opener of the discussion on climate marks the greater importance of the discussion upon sanatoriums. In the congregations of the sanatorium said Professor T Clifford Allbutt, we have learnt individual treatment. The lesson expounded by Professor Allbutt with lucidity and eloquence has been published in full already in our pages[1] But little was added by subsequent speakers to his admirable exposition. He laid no special stress upon any one of the factors in treatment whether air rest, food, exercise, or mental influence, as worthy of greater attention than another how rightly is evident, for of those speakers who expressed their esteem for one agency as more influential than others one mentioned air another rest, and a third feeding Each factor was said to require skilful use and to be capable of abuse, the warning being given to avoid a sanatorium when detailed attention gives way to simple routine. Rules said *Dr Huggard* are a poor substitute for principles.

What are the results of the treatment? Good very good no doubt, but duration of recovery the only test, has not in this country had opportunity of expression. Dr F W Burton Fanning made a gallant attempt in giving the data of 12 British sanatoriums and in drawing up his report in a *form* that appears to us to be a closer approximation to precision of statistical information than has hitherto been published. He has forsaken the old first second and third stages as the basis of classification and has *taken three classes upon which there can be no difference of* opinion when future investigators make comparison —(1) cases with habitual rise of temperature to 99 6° or higher (2) cases with rapid cardiac action without fever and (3) cases without fever or rapid cardiac action 25 per cent. (1) 4 per cent. (2) and 63 per cent. (3) were the relative recovery rates. Over 700 cases are reported upon from British sanatoriums, about 400 cases of high altitude treatment are reported upon by Dr Theodore Williams and 150 by Dr Stephani. The groups are not perhaps upon a sufficiently similar basis for comparison it is remarkable that the arrest, quiescence amelioration cure and half cure total up to 77 75 and 62 per cent. in these three instances of statistics and results.

Dr J Kingston Fowler drew attention to the most important item in the report on British sanatoriums 'Only 52 patients can be described as cases of slight lung mischief 46, or 88 4 per cent. of these patients with strictly limited disease did well and attained relative recovery with arrest of their disease. Every trustworthy report from sanatoriums said Professor Allbutt, emphasises anew the remarkable success of Brehmer s system on one condition—namely that the patient be caught at the outset of his disease. In diphtheria *this lesson has been learnt, but energy in attacking* early phthisis is yet often unappreciated. Again, Dr W \ Snow reported the result of initiating this treatment at the National Sanatorium of Bournemouth In the early stages 63 per cent. showed apparent arrest of the disease and in 93 per cent. improvement, and this despite many leaving a the end of three months. However cheering such calculations may be they are even less convincing than is the ample evidence observed by many a pathologist that recovery is commoner than fatality in every-day life

How are the results of sanatorium treatment gained? By perfect sanitation skilled alimentation and controlled metabolism these Sir R. Douglas Powell in conclusion said had been in part taken for granted in part largely dwelt upon with additional light. The alimentation factor received more elucidation than any The clinical precaution of Professor Allbutt to examine the size of the stomach before and after a meal, so that its powers of disposing of food may be gauged and the marking the weight that ought to be gained by a limit estimated at the normal healthy weight of the patient as recommended by Dr Burton-Fanning are good methods to practise. That increase of weight *per se* tells little as to the future of the patient seems probable seeing that Dr Rosenthal's patients in the second stage gained as much as, or more than, those in the first stage, that might be owing to a start further away from their normal weight. The increase of weight in different sanatoriums is not proportionate to the fulness of diet provided according to the results in the United Kingdom, nor does it bear a constant relation to the recovery rate

---

[1] THE LANCET Nov 9th 1901 p 1253

Such facts as the above call for explanation and proclaim a want of guidance in the control of the daily intake of food. Dr Noel D Bardswell was able to render information with the precision and certainty that belongs to prolonged analytical investigations He gave a *resumé* of the paper written in collaboration with Dr F W Goodbody and Mr J E Chapman which had been read before the Royal Medical and Chirurgical Society a month previously In that paper the metabolism of six persons can be fully followed through different diets, the general statements based upon such thorough data are worthy of full attention though they may not be entirely novel statements Appetite gives too low an estimate of requirement. In any case a very large diet is unsatisfactory Full diets but not too large diets gave the bests results [2] It appears to be advisable to diminish the amount of food as the disease becomes quiescent and the patient approaches normal weight, but even at this period he will require a more substantial diet than when he is in health

The factors of treatment other than diet receive little more than mere mention in the proceedings Professor Allbutt had propounded many questions of a most practical and important kind "Can mixed infections be recognised from fever curves?" "What estimates of improvement and what rules of prognosis can be based upon physical signs alone?" and many others, but discussion drifted away usually into the domain of State medicine We gather some valuable information as to what was being done in different countries by their distinguished representatives—in Austria by Professor von Schrötter, in Bohemia by Dr Dvorak, in New York by Professor Janeway and Dr Knopf, in Massachusetts by Dr Stone, in Copenhagen by Dr Rosenthal, in Germany by Dr Becher and Dr Lennhoff, in Switzerland by Dr Morin, and in France by Dr Verhaeren, Dr Frottier, Dr Lasalle, and Dr Baradat. Many counsels of perfection are advocated by these contributors, enough to show that far more remains to be done possibly until we get so far as classifying our sanatoriums as pointed out by Dr Kuss Meanwhile it would be well if we could supply the still urgent want, the want of knowledge, by establishing a freemasonry of investigation and information among sanatoriums —a plan in which apparently the sanatoriums of France have anticipated the demand of Professor Clifford Allbutt

(*To be continued*)

THE CREMATION ACT, 1902

THE following is the text of the Cremation Act which recently received the Royal Assent —

2 EDW VII CHAPTER 8

An Act for the regulation of the burning of human remains and to enable burial authorities to establish crematoria (22nd July, 1902.)

Be it enacted by the King's most Excellent Majesty by and with the advice and consent of the Lords Spiritual and Temporal and Commons in this present Parliament assembled, and by the authority of the same as follows:—

1 This Act may be cited as the Cremation Act 1902.

2. In this Act the expression burial authority shall mean any burial board, any council, committee or other local authority having the powers and duties of a burial board, and any local authority maintaining a cemetery under the Public Health (Interments) Act 1879 or under any local Act The expression crematorium shall mean any building fitted with appliances for the purpose of burning human remains, and shall include everything incidental or ancillary thereto

3 In the application of this Act to Scotland the expression burial authority" shall mean the parish council or town council of any parish or burgh as the case may be vested with the powers and duties conferred by the Burial Grounds (Scotland) Act 1855, or any Act amending the same the expression the Local Government Board shall mean the Local Government Board for Scotland the expression Secretary of State" shall mean the Secretary for Scotland

4 The powers of a burial authority to provide and maintain burial grounds or cemeteries or anything essential ancillary or incidental thereto shall be deemed to extend to and include the provision and maintenance of crematoria provided that no human remains shall be burned in any such crematorium until the plans and site thereof have been approved by the Local Government Board and until the crematorium has been certified by the burial authority to the Secretary of State to be complete built in accordance with such plans, and properly equipped for the purpose of the disposal of human remains by burning

5 No crematorium shall be constructed nearer to any dwelling-house than 200 yards, except with the consent in writing of the owner, lessee and occupier of such house, nor within 50 yards of any public highway nor in the consecrated part of the burial ground of any burial authority

6 A burial authority may accept a donation of land for the purpose of a crematorium and a donation of money or other property for enabling them to acquire, construct or maintain a crematorium

7 The Secretary of State shall make regulations as to the maintenance and inspection of crematoria and prescribing in what cases and under what conditions the burning of any human remains may take place, and directing the disposition or interment of the ashes, and prescribing the forms of the notices certificates and declarations to be given or made before any such burning is permitted to take place such declarations to be made under and by virtue of the Statutory Declarations Act, 1835 and also regulations as to the registration of such burnings as have taken place A copy of such regulations shall be laid before both Houses of Parliament, if Parliament be then sitting or if not then within three weeks after the beginning of the next ensuing session of Parliament, and after such regulations have lain for 40 days before Parliament, then, unless within such 40 days an address has been presented by one or other of the said Houses praying His Majesty to withhold his assent from such regulations or any part thereof, such regulations shall have the same effect as if they were enacted in this Act All statutory provisions relating to the destruction and falsification of registers of burials and the admissibility of extracts therefrom as evidence in courts and otherwise shall apply to the register of burnings directed by such regulations to be kept and the Stamp Act, 1891, shall apply to a register under this Act as if it were a register of burials
